Draft assessment report regarding durvalumab in combination with PDC for perioperative treatment of resectable non-small cell lung cancer

AstraZeneca would like to thank DMC for the assessment of durvalumab in the above-mentioned setting and appreciates the opportunity to comment on the draft assessment report.

Initially AstraZeneca would like to emphasize that as there are no other products available for perioperative treatment of resectable NSCLC that has been approved by DMC and as the relevance of the clinical studies on the approved products in the neoadjuvant and adjuvant respectively only to a certain extend are relevant as basis for an indirect treatment comparison, in general it is a challenge to perform an optimal analysis. Based on this, the application included 3 different comparators (neoadjuvant PDC, neoadjuvant nivolumab plus PDC and adjuvant PDC) in order to try and provide as detailed a picture of the relative benefit of durvalumab in this perioperative indication as possible.

In the assessment report, DMC mention that durvalumab is most likely to have more serious AEs compared to nivolumab in the AEGEAN and CheckMate-816 study regime respectively and mention that longer treatment duration may associate with more toxicity. However, AEGEAN and CheckMate-816 differ materially, e.g. stage distribution, TNM version, number of neoadjuvant cycles, platinum agent, and regional composition. As acknowledged in the assessment report, unadjusted direct comparisons between the two studies are not justified. Similarly, without appropriate statistical methods, any conclusions should not be drawn for safety comparisons. Notably, in AEGEAN, the control arm - which received no active treatment other than placebo after surgery - showed similar rates of serious adverse events as the intervention arm. This indicates that adjuvant durvalumab monotherapy after surgery did not contribute additional serious toxicity.

DMC notes that the AEGEAN study population may not be fully generalizable to Danish clinical practice for resectable NSCLC (e.g., higher proportions of stage III/N2, multiregional enrolment, and differences in neoadjuvant chemotherapy composition). These factors may attribute to uncertainty about real world effectiveness. However, no additional evidence is provided by the DMC in the evaluations report that would suggest the benefits of Durvalumab as a perioperative treatment would be overestimated, compared to standard of care in the Danish clinical setting.

In general, AstraZeneca considers that the patient population in scope has a potential severe prognosis, with a five-year survival between 46% and 57%, despite patients being treated with IO in the neoadjuvant phase. As this is a developing area, AstraZeneca has proposed to collect further evidence via an innovative agreement (conditional recommendation) to support the decision to use perioperative treatment of NSCLC in Danish clinical practice.

We look forward to receiving the DMC decision with the hope that durvalumab will be made available for patients with resectable NSCLC, and that DMC sees the relevance of providing more evidence on possible selection criteria for eligible patients for perioperative treatment.

Kind regards,

Mette Lange, Market Access Manager

Konkurrencesituationen

Der er på nuværende tidspunkt ikke andre lægemidler anbefalet som peri-operativ behandling af NSCLC. Keytruda (pembrolizumab) er tidligere blevet vurderet til samme indikation af Medicinrådet, men blev ikke anbefalet.

Opdivo i kombination med kemoterapi er anbefalet af Medicinrådet til neoadjuverende behandling af patienter med PD-L1 ≥ 1 %, men patienter som får neoadjuverende behandling, skal ikke tilbydes adjuverende behandling efter operation jf. Medicinrådets anbefaling. Tecentriq (atezolizumab) er anbefalet som adjuverende behandling til patienter med PD-L1 ≥ 50 %.

Tabel 2 viser lægemiddeludgifter for hhv. neoadjuverende og adjuverende behandling. For neoadjuverende behandling gives behandling med Imfinzi i 4 serier (svarende til 12 uger), mens behandling med Opdivo gives i 3 serier (svarende til 9 uger). For adjuverende behandling gives behandling med Imfinzi i højst 12 serier (svarende til 48 uger), mens behandling med Tecentriq gives i højst et år (svarende til 52 uger). Tabel 2 nedenfor viser den samlede lægemiddeludgift for de enkelte behandlingsregimer beregnet på den maksimale behandlingslængde, behandlingsvarigheden er derfor ikke ens. Lægemiddeludgifter til kombinationsbehandling med kemoterapi er ikke medtaget i beregningen.

Tabel 2: Sammenligning af lægemiddeludgifter pr. patient for hhv. neoadjuverende og adjuverende behandling af NSCLC.

Lægemiddel	Styrke (pakningsstørrelse)	Dosering	Pris pr. pakning (SAIP, DKK)	Lægemiddeludgift pr. behandlingsregime (SAIP, DKK)
Neoadjuverende behandling				
Imfinzi	50 mg/ml (2,4 ml)	1.500 mg (i.v.) hver 3. uge i 4 serier *12 ugers behandling*	[redacted]	[redacted]

1. Regulatory information on the medicine

Overview of the medicine	
Proprietary name	Imfinzi®
Generic name	Durvalumab
Therapeutic indication as defined by EMA	Imfinzi® (durvalumab) in combination with platinum-based chemotherapy as neoadjuvant treatment, followed by durvalumab monotherapy as adjuvant treatment, is indicated for the treatment of adults with resectable non-small cell lung cancer (rNSCLC) at high risk of recurrence and no epidermal growth factor receptor (EGFR) mutations or anaplastic lymphoma kinase (ALK) rearrangements [1].
Marketing authorization holder in Denmark	AstraZeneca
ATC code	L01FF03
Combination therapy and/or co-medication	Neoadjuvant platinum-based doublet chemotherapy (PDC) [1].
(Expected) Date of EC approval	31/03/2025
Has the medicine received a conditional marketing authorization?	No
Accelerated assessment in the European Medicines Agency (EMA)	No
Orphan drug designation (include date)	No
Other therapeutic indications approved by EMA	NSCLC: • Durvalumab as monotherapy is indicated for the treatment of locally advanced, unresectable NSCLC in adults whose tumours express PD-L1 on ≥ 1% of tumour cells and whose disease has not progressed following platinum-based chemoradiation therapy. • Durvalumab in combination with tremelimumab and platinum-based chemotherapy is indicated for the first-line treatment of adults with metastatic

Overview of the medicine	
	NSCLC with no sensitising EGFR mutations or ALK positive mutations. Small Cell Lung Cancer (SCLC): • Durvalumab as monotherapy is indicated for the treatment of adults with limited-stage small cell lung cancer (LS-SCLC) whose disease has not progressed following platinum-based chemoradiation therapy. • Durvalumab in combination with etoposide and either carboplatin or cisplatin is indicated for the first-line treatment of adults with extensive-stage small cell lung cancer (ES-SCLC). Biliary Tract Cancer (BTC): • Durvalumab in combination with gemcitabine and cisplatin is indicated for the first line treatment of adults with unresectable or metastatic BTC. Hepatocellular Carcinoma (HCC): • Durvalumab as monotherapy is indicated for the first line treatment of adults with advanced or unresectable HCC. • Durvalumab in combination with tremelimumab is indicated for the first line treatment of adults with advanced or unresectable HCC. Endometrial Cancer (EC): Durvalumab in combination with carboplatin and paclitaxel is indicated for the first-line treatment of adults with primary advanced or recurrent endometrial cancer who are candidates for systemic therapy, followed by maintenance treatment with: • Durvalumab as monotherapy in endometrial cancer that is mismatch repair deficient (dMMR) • Durvalumab in combination with olaparib in endometrial cancer that is mismatch repair proficient (pMMR).
Other indications that have been evaluated by the DMC (yes/no)	Yes, in the following indications: NSCLC: On May 30, 2025 DMC recommended durvalumab for stage III NSCLC in adults with

Overview of the medicine	
	PD-L1 ≥ 1% and whose disease has not progressed following platinum based chemoradiation therapy SCLC: On September 25, 2024, the DMC recommended durvalumab in combination with etoposide and either carboplatin or cisplatin for the first-line treatment of adults with ES-SCLC. BTC: On 04 March 2025, the DMC recommended durvalumab in combination with gemcitabine and cisplatin for the first-line treatment of adults with unresectable or metastatic BTC in performance status 0 or 1. HCC: On 05 December 2024, the DMC recommended durvalumab in combination with tremelimumab for the first-line treatment of adults with advanced or unresectable HCC. EC: On May 2, 2025, the DMC recommended Durvalumab in combination with carboplatin and paclitaxel for the first-line treatment of adults with primary advanced or recurrent endometrial cancer. Ongoing assessments by DMC: SCLC: Durvalumab as monotherapy for the treatment of adults with LS-SCLC whose disease has not progressed following platinum-based chemoradiation therapy.
Joint Nordic assessment (JNHB)	Are the current treatment practices similar across the Nordic countries (DK, FI, IS, NO, SE)? Yes Is the product suitable for a joint Nordic assessment? No, as this assessment includes an indication extension for Imfinzi® and follows the DMC 14-week assessment process without a health economic assessment.
Dispensing group	BEGR
Packaging – types, sizes/number of units and concentrations	N/A

2. Summary table

Summary	
Indication relevant for the assessment	Durvalumab in combination with platinum-based chemotherapy as neoadjuvant treatment, followed by durvalumab as monotherapy as adjuvant treatment, for the treatment of adults with rNSCLC at high risk of recurrence and no EGFR mutations or ALK rearrangements [1].
Dosage regiment and administration	Durvalumab should be administered intravenously in combination with platinum-based chemotherapy at a dose of 1,500 mg every three weeks for up to four cycles prior to surgery, followed by 1,500 mg monotherapy every four weeks for up to 12 cycles after surgery [1]. Treatment should be given in the neoadjuvant phase until disease progression that precludes definitive surgery, unacceptable toxicity, or maximum of four cycles and in the adjuvant phase until recurrence, unacceptable toxicity or a maximum of 12 cycles after surgery [1].
Choice of comparator	1. Neoadjuvant platinum-based doublet chemotherapy (PDC) 2. Neoadjuvant nivolumab plus PDC (PD-L1 ≥ 1%) 3. Adjuvant PDC.
Prognosis with current treatment (comparator)	Surgical resection with curative intent is recommended for patients with Stage I-III NSCLC [2, 3]. Despite the curative intent of surgery and the addition of neoadjuvant or adjuvant systemic therapy, recurrence rates remain high, and PDC offers only modest benefit in reducing recurrence or death [4-7]. Immuno-oncology (IO) therapies have shown improved outcomes in both neoadjuvant and adjuvant settings [8-12], but neoadjuvant IO is reserved for a subgroup of patients with PD-L1 ≥ 1% in Denmark. In Denmark, about 35% experience recurrence after surgery. Overall, ~40% of NSCLC patients treated with curative intent relapse within five years and only ~20% are eligible for curative retreatment, and the five-year survival for stage IIA–IIIA rNSCLC is 46%-57% [13, 14].
Type of evidence for the clinical evaluation	Head-to-head study AEGEAN (NCT03800134) for perioperative durvalumab versus neoadjuvant PDC. An indirect treatment comparison (ITC) versus neoadjuvant nivolumab + PDC (CheckMate 816 NCT02998528) and versus adjuvant PDC (NATCH NCT00913705).

Summary	
Most important efficacy endpoints (Difference/gain compared to comparator)	Perioperative durvalumab versus neoadjuvant PDC HR in EFS, 0.69 (95% CI: 0.55, 0.88) [15, 16]. [redacted]
Most important serious adverse events for the intervention and comparator	The most common serious adverse events (SAEs) in AEGEAN were infections and infestations, pneumonias, blood and lymphatic system disorders and respiratory disorders. In the CheckMate 816 trial, the overall incidence of SAEs was 17% for nivolumab + chemotherapy and 14% for chemotherapy alone. No serious adverse events were reported in NATCH for adjuvant chemotherapy.
Impact on health-related quality of life	Patient reported outcomes (PRO) were included as secondary endpoints in the AEGEAN study measured in the neoadjuvant period, with European Organisation for Research and Treatment of Cancer (EORTC): 1) Quality of Life Questionnaire Core 30 (QLQ-C30) and 2) Quality of Life Questionnaire Lung Cancer 13 (QLQ-LC13) module [17]. In CheckMate 816, health related quality of life (HRQoL) was an exploratory endpoint with the EuroQoL 5 dimension 3 levels and Visual Analogue Scale (EQ-5D-3L VAS) questionnaire [18]. In both AEGEAN and CheckMate 816 studies, HRQoL scores were generally similar between treatment arms throughout the neoadjuvant and adjuvant periods, with no clinically meaningful or consistent differences observed. The NATCH trial did not collect QoL data.

3. The patient population, intervention, choice of comparator(s) and relevant outcomes

3.1 The medical condition

Non-small cell lung cancer (NSCLC) is the most common type of lung cancer, accounting for between 80% to 90% of cases [19-23]. Lung cancer is categorised according to the American Joint Committee on Cancer (AJCC) staging criteria, which utilise the tumour, (lymph) node, metastasis (TNM) system [24, 25]. Patients with Stage I–III NSCLC, representing ~30% of patients at diagnosis [26-29], are considered resectable and amenable to surgery with curative intent, referred to as rNSCLC. The goal is to completely remove the primary tumour and any involved regional lymph nodes [2, 30, 31]. This strategy is recommended by the European Society for Medical Oncology (ESMO), the National Comprehensive Cancer Network (NCCN) and the Danish Lung Cancer Groups (DLCG) treatment guidelines for patients with Stage I-IIIA, and in selected cases, for stage IIIB (AJCC TNM 8th edition) [2, 30, 31]. In Denmark, approximately 30% of patients are diagnosed with local disease (Stage IIA-IIIA), and 25% present with locally advanced disease (IIIA-IIIC) [13, 14].

Systemic therapy can be administered before (neoadjuvant) or after (adjuvant) surgery to reduce the risk of recurrence and improve the chances of cure. It is typically offered to patients at higher risk of recurrence. The definition of high risk of recurrence is based on lymph node involvement, tumour size, and other tumour characteristics [2, 31, 32], as per the AJCC TNM 8th edition [1]: Tumour size ≥ 4 cm and N1 or N2 disease (regardless of

primary tumour size), including multi-station N2; patients with multiple tumour nodules in the same lobe or tumours that involve the main bronchus or tumours that invade visceral pleura, chest wall (including the parietal pleura and superior sulcus tumours), phrenic nerve or parietal pericardium; or tumours that are associated with atelectasis or obstructive pneumonitis that extends to the hilar region or involves part or all of the lung [1].

Despite the curative intent of surgery and the addition of systemic therapy, recurrence rates remain high, and the addition of PDC in the neoadjuvant or adjuvant setting has resulted in only modest reductions in the risk of recurrence or death [4-7]. In Denmark, approximately 35% have recurrence after surgery, and ~ 40 % of those who are treated for NSCLC with curative intent in Denmark will experience a recurrence within 5 years after surgery. Of these, only about 20% will be candidates for renewed potential curative treatment [33]. Once recurrence occurs, curative-intent therapy is generally no longer feasible, particularly in patients with metastatic disease [2, 31]. Consequently, the prognosis after recurrence is very poor [34-36]. The risk of recurrence is highest in the initial years following surgery and is further elevated in more advanced stages of NSCLC. By five years post-surgery, the risk of recurrence decreases substantially [37-40].

In Denmark, the overall five-year survival rate for lung cancer is 26% [49, 50], and the five-year survival following surgery is 64% [47]. For patients with recurrent Stage IIA-IIIA rNSCLC, five-year survival is estimated between 46% and 57% [34, 35].

IO regimens in the neoadjuvant setting or in the adjuvant setting have been shown to reduce recurrence rates after surgery [8, 9, 11, 12, 41]. Notably, neoadjuvant IO may offer an advantage over adjuvant IO by priming anti-tumour immunity while the primary tumour and regional lymph nodes are still present [42]. Despite these improvements, outcomes remain suboptimal, and there is room for further advancement. The perioperative approach, which integrates neoadjuvant IO (in combination with chemotherapy), surgery, and subsequent adjuvant IO, may provide additional clinical benefit compared to neoadjuvant IO alone or adjuvant chemotherapy. This strategy aims to consolidate the immune response and maintain suppression/eradication of residual cancer cells after surgery [43, 44]. As such, the perioperative approach offers a more comprehensive treatment strategy to maximise the chances of successful long-term outcomes for patients treated with curative intent.

3.2 Patient population

The relevant patient population for this application is adults with rNSCLC at a high risk of recurrence and no EGFR mutations or ALK rearrangements, which aligns with the population in the pivotal clinical trial AEGEAN [16].

Of all patients diagnosed with lung cancer in Denmark (approximately 4,900), 85% are diagnosed with NSCLC [3, 13, 14]. In the latest report from the Danish Lung Cancer Register, the incidence (patients diagnosed) of NSCLC was 4,161 in 2023. Table 1 gives an overview of the incidence in Denmark over the last five years. As no incidence have been presented from the register for 2024, the 2023 estimate was used. The proportion of

NSCLC patients who underwent curative intent treatment, defined as either resection or curatively intended oncological treatment (e.g., radiotherapy), was relatively stable, around 28% [45-47]. Of all patients with NSCLC, it has been estimated that 30% have local disease (stage II-IIIA) and 25% have locally advanced disease (stage IIIA-IIIC) [13, 14].

Table 1 Incidence and prevalence in the past 5 years

Year	2020	2021	2022	2023	2024
Incidence in Denmark	4,876	4,075	4,103	4,161	4,161*
Prevalence in Denmark	N/A	N/A	N/A	N/A	N/A
Global prevalence	N/A	N/A	N/A	N/A	N/A

Note: The estimate for the incidence in 2020-2023 are based on the number of patients diagnosed with NSCLC presented in the Danish Cancer Register yearly reports. *The incidence estimated for 2024, is based on 2023.

Source : Danish Lung Cancer Register, DLCG yearly reports 2019-2020 [45], 2021 [46], and 2023 [47].

When calculating the expected number of eligible patients for durvalumab + platinum-based doublet chemotherapy (PDC) as neoadjuvant treatment, followed by durvalumab as monotherapy as adjuvant treatment, in adults with rNSCLC at high risk of recurrence and no EGFR mutations or ALK rearrangements, it was assumed that only stage III (stage IIIA–IIIB) patients would be treated during the first five-year period. This assumption is based on the current use of neoadjuvant nivolumab + PDC in Denmark, which is primarily administered to stage III patients. The following steps were used to estimate the number of eligible patients for rNSCLC SCLC who are eligible for treatment with durvalumab in Denmark:

- Lung cancer incidence (total): 5,125 patients
- NSCLC cases (80%): ≈ 4,100 patients
- Stage IIIA–IIIB (<N3) subset (12%): ≈ 492 patients
- Resectable patients (32%): ≈ 154 patients
- EGFR-wildtype (92%): ≈ 142 patients
- Receiving systemic drug therapy (85%): ≈ 121 patients
- Perioperative treatment share (40%): ≈ 48 patients
- Expected to receive IO (90%): ≈ 44 patients
- Estimated treated in Year 1 (based on rollout phase-in): ≈ 10 patients (Table 2):

Over time as perioperative treatment with IO is expected to increase, stage II patients will be treated in accordance with the durvalumab indication. When including the stage II patients, an additional 43 patients with perioperative IO is estimated of which 22% (9 patients) are assumed to be treated with durvalumab.

In previous assessments by the DMC, larger patient numbers have been estimated for perioperative and neoadjuvant IO in resectable NSCLC [48, 49]. In the assessment of

perioperative pembrolizumab + PDC, for stage II–IIIB NSCLC regardless of PD-L1 expression, the eligible patient population was estimated to 242–300 patients per year [49]. These estimates, however, do not account for patients who may not receive systemic therapy or who are ineligible for IO. In the assessment of neoadjuvant nivolumab in combination with PDC (hereafter referred to neoadjuvant nivolumab + PDC), which is recommended only for resectable NSCLC with PD-L1 ≥ 1%, the DMC estimated around 120 patients per year to be eligible [48].

The DMC, however highlight that in practice, only 40 to 50 patients annually are treated with neoadjuvant IO [48]. While previous estimates for neoadjuvant IO suggest a higher number of eligible patients, the perioperative estimates presented here are more conservative, including only stage III, EGFR-wildtype and systemic therapy use, leading to lower numbers that might increase as the use of perioperative IO broadens. We assumed 20% of the patients who received neoadjuvant therapy might be eligible for peri-operative therapy. Neoadjuvant IO has been used only for a short period of time in Denmark, so it is challenging to estimate the proportion at this point of time.

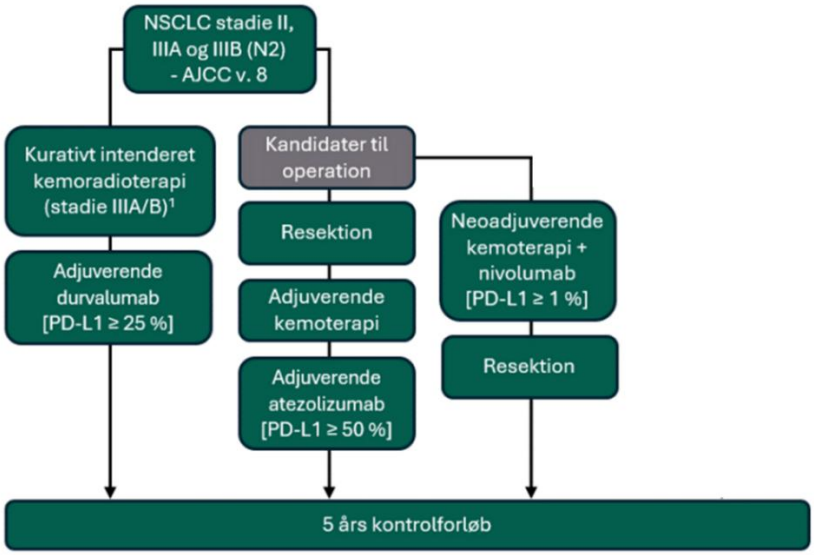
Table 2 Estimated number of patients eligible for treatment

Year	Year 1	Year 2	Year 3	Year 4	Year 5
Number of patients in Denmark who are eligible for treatment in the coming years	10	10	10	10	10

3.3 Current treatment options

According to Danish treatment guidelines, patients with local or locally advanced NSCLC typically receive curative-intent treatment, which may involve surgery or chemoradiotherapy (CRT) [3, 13, 14]. An overview of the current treatment options is provided in Figure 1.

Figure 1 Current treatment algorithm and treatment options in Danish clinical practice



Source: Adapted from DMC assessment of perioperative pembrolizumab in adults with rNSCLC [49]

Abbreviation: PD-L1: Programmed Death-ligand 1;NSCLC: Non-small Cell Lung cancer

In Denmark, neoadjuvant treatment with nivolumab + PDC is recommended for operable patients with Stage II-IIIA (AJCC TNM 8th edition), PD-L1 expression ≥1%, and harbouring no targetable mutations [13]. Surgery should be performed within six weeks after completion of neoadjuvant therapy. This approach aims to improve outcomes by administering oncological therapy prior to surgery. The decision to initiate neoadjuvant therapy should always be made within a multidisciplinary medical team [13]. In general, patients who have received neoadjuvant treatment are not offered adjuvant therapy, though close follow-up is advised [13]. For patients who undergo surgery without prior neoadjuvant therapy, the adjuvant treatment strategy depends on stage and individual risk factors [14].

Adjuvant chemotherapy should be offered to NSCLC with stage IB, IIA (tumour >4cm), IIB and stage III disease (TNM 8th edition). PDC should be initiated 4-8 weeks post-surgery. The preferred regimen is cisplatin in combination with vinorelbine. If cisplatin is not suitable due to patient comorbidities or tolerability, carboplatin may be used as an alternative. Stage I patients may also be considered for adjuvant chemotherapy depending on recurrence risk. Stage II patients may receive adjuvant chemoradiotherapy in certain cases. Additionally, patients across stages I-III who are disease-free following curative treatment may be offered postoperative radiotherapy as part of adjuvant management.

In patients who have undergone curative-intent surgery, adjuvant immunotherapy may be offered to those at high risk of recurrence, provided they have [14]:

- Received platinum-based chemotherapy
- Tumours express PD-L1 ≥50%
- No EGFR mutations or ALK translocations.

In these cases, treatment with atezolizumab, an immune-check inhibitor, should begin within 8 weeks after completing adjuvant chemotherapy and continue for up to one year [14]. Close follow-up is recommended for all patients following curative treatment, particularly during the first two years, due to the elevated risk of local recurrence during this period [14].

Patients with stage III NSCLC who have undergone curative CRT and have PD-L1 Tumor Proportion Score (TPS) ≥25%, and no evidence of disease progression, may be eligible for adjuvant treatment with durvalumab for up to 12 months [14].

3.4 The intervention

Durvalumab is a high-affinity, human, recombinant IgG1κ monoclonal antibody that selectively blocks the interaction between PD-L1 and its receptors, PD-1 and CD80 (B7.1) [50]. PD-L1 is often overexpressed on tumour cells and antigen-presenting cells in the tumour microenvironment, where it downregulates immune responses by inhibiting T-cell activation. By preventing this interaction, durvalumab enhances T-cell-mediated immune responses against tumour cells, restoring cytotoxic activity, proliferation, and cytokine production [1, 50, 51].

The combination of PDC and durvalumab is believed to enhance anti-tumour responses through immunogenic effects and upregulation of PD-L1 expression, which may increase tumour sensitivity to immune checkpoint blockade. Chemotherapy-induced tumour cell death can promote antigen presentation, while increased PD-L1 expression may improve the efficacy of anti-PD-(L)1 therapies in poorly immunogenic tumours [52, 53]. Combining immunotherapy with chemotherapy has shown superior anti-tumour activity and response rates and may also help reduce the risk of treatment resistance [54, 55]. Clinical trial data in metastatic Stage IV NSCLC supports the effectiveness of this combination, suggesting potential utility in earlier treatment settings as well [56-59].

An overview of the intervention is provided in Table 3 below.

Table 3 Overview of the intervention, durvalumab (Imfinzi®)

Overview of intervention	
Indication relevant for the assessment	Durvalumab in combination with platinum-based chemotherapy as neoadjuvant treatment, followed by durvalumab monotherapy as adjuvant treatment, indicated for the treatment of adults with rNSCLC at high risk of recurrence and no EGFR mutations or ALK rearrangements [60]
ATMP	N/A
Method of administration	IV

Overview of intervention	
Dosing	Maximum of four cycles of PDC with durvalumab (1,500 mg) IV every three weeks, followed by surgery. Following surgery, durvalumab (1,500 mg) IV every four weeks for up to 12 cycles.
Dosing in the health economic model (including relative dose intensity)	N/A
Should the medicine be administered with other medicines?	Durvalumab is used in combination with platinum-based chemotherapy as neoadjuvant treatment.
Treatment duration / criteria for end of treatment	Prior to surgery patients receive up to four cycles of treatment every 3 weeks (12 weeks in total). Post-surgery patients can receive up to 12 cycles of treatment, with treatment every 4 weeks (total of 48 weeks).
Necessary monitoring, both during administration and during the treatment period	Patients are monitored during the administration of the drugs and during the course of the treatment period.
Need for diagnostics or other tests (e.g. companion diagnostics). How are these included in the model?	The relevant biomarkers for ALK, EGFR mutations and PD-L1 expression are standard tests for these patients. Thus, no new tests are needed. N/A, as no CE-model is included in this application.
Package size(s)	50 mg/ml, 10 ml vial and 50 mg/ml, 2.4 ml vial.

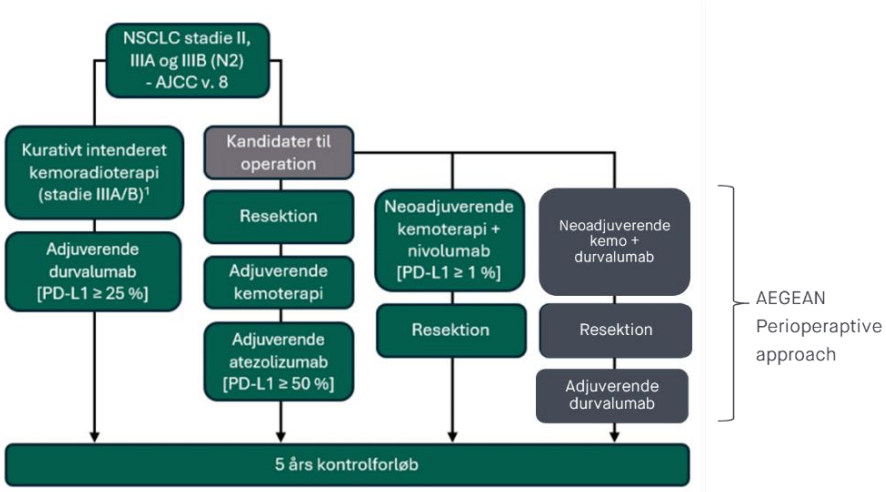
3.4.1 Description of ATMP

N/A

3.4.2 The intervention in relation to Danish clinical practice

When considering a perioperative setting (neoadjuvant therapy, surgery and adjuvant therapy), current clinical practice in Denmark includes the use of either neoadjuvant or adjuvant treatment (as presented previously in section 3.3 and Figure 1). The current standard of care (SoC) in the adjuvant setting consists of PDC. In Denmark the preferred PDC consist of cisplatin or carboplatin in combination with vinorelbine. In the neoadjuvant setting, PDC without nivolumab may still be considered in selected cases, for instance in patients with large tumours and N0 disease, where the intent is to reduce surgical morbidity (e.g., tumours adjacent to the chest wall). However, following the approval of neoadjuvant nivolumab + PDC by DMC, this has become the predominant SoC for patients with PD-L1 ≥1% [13]. The expected place in therapy for durvalumab + PDC as neoadjuvant treatment, followed by durvalumab monotherapy as adjuvant treatment after surgery, for adults with rNSCLC at high risk of recurrence and no known EGFR mutations or ALK gene rearrangements is presented in Figure 2.

Figure 2 Place in current treatment algorithm



3.5 Choice of comparator(s)

Durvalumab is indicated in combination with PDC (hereafter referred to as durvalumab + PDC or perioperative durvalumab) as neoadjuvant treatment, followed by durvalumab as monotherapy as adjuvant treatment, for the treatment of adults with rNSCLC with no known EGFR mutations or ALK gene rearrangements and at high risk of recurrence.

As there are currently no nationally recommended treatments in the perioperative setting, the three comparators selected in this assessment are in line with DLCG treatment guidelines: neoadjuvant PDC (Comparator 1, see Table 4), neoadjuvant nivolumab + PDC in PD-L1 ≥1% (Comparator 2, see Table 5), and adjuvant PDC (Comparator 3, see Table 6).

Comparator 1, neoadjuvant PDC, follows the Danish clinical recommendations [3, 13] with cisplatin combined with vinorelbine as the first-choice regimen, since cisplatin causes less bone marrow toxicity than carboplatin. However, if cisplatin is not tolerated, carboplatin may be used in combination with vinorelbine. **Comparator 2**, neoadjuvant nivolumab + PDC, is recommended as SoC by the Danish guidelines in PD-L1 ≥1% [3, 13], with nivolumab administered at a dose of 360 mg alongside the same PDC regimen as, described for Comparator 1. **Comparator 3**, adjuvant PDC, is recommended as SoC by the Danish guidelines [14], the choice of PDC regimen can vary, but the preferred PDC is a as previously described for Comparator 1.

Other comparators were considered but excluded from the assessment. These included adjuvant atezolizumab following adjuvant chemotherapy, and CRT. Adjuvant atezolizumab treatment was not considered relevant, as results from the IMpower010 trial were not viewed as clinically convincing by clinical experts in Denmark [Section 14]. For example, at a median follow-up of 45.3 months, 25% of patients treated with atezolizumab had died, compared to a similar proportion of 24.9% in the best supportive care (BSC) treatment arm [61]. The 3-year disease-free survival (DFS) was 56% for the atezolizumab arm and 49% BSC, with a more pronounced effect observed in the PD-L1 ≥

50% subgroup, which showed a 3-year DFS of 75.1% compared to 50.4% [14, 61]. However, this subgroup does not align with the target population in this assessment.

Lastly, according to Danish guidelines, chemoradiotherapy is generally recommended only for patients who are not eligible for surgery or who decline surgical treatment, and is therefore not relevant as a comparator [3].

The other comparators considered were also discussed prior to the submission with DMC, who stated that although several comparators could be considered, it was acknowledged that not all could be expected to be included in this application.

Table 4 Overview of Comparator 1 - Neoadjuvant platinum-based chemotherapy

Overview of comparator	Cisplatin	Carboplatin	Vinorelbine
Generic name	Cisplatin "Accord"	Carboplatin "Accord"	Vinorelbine "Accord"
ATC code	L01XA01	L01XA02	L01CA04
Mechanism of action	Cisplatin binds directly to DNA, creating cross-links that block replication and transcription, leading to the death of cancer cells.	Carboplatin alters the supercoiled structure of DNA, disrupting replication and inhibiting the growth of cancer cells.	Vinorelbine blocks cancer cell division by disrupting microtubels, which are needed to separate chromosomes. This leads to cell death and slows tumour growth.
Method of administration	Intravenous infusion	Intravenous infusion	Orally
Dosing	80 mg/m², is given day 1 followed by every 22 days for 4 treatment cycles [62].	5* (GFR+25 mg), given day 1 and then at day 22 when a new cycle begins, 4 cycles in total [63].	60 mg/m², given on day 1 and 8 every cycle. Cycle is repeated 4 times [62].
Dosing in the health economic model (including relative dose intensity)	N/A	N/A	N/A
Should the medicine be administered with other medicines?	Can be administered together with vinorelbine.	Administered with vinorelbine.	Administered together with cisplatin or carboplatin.

Overview of comparator	Cisplatin	Carboplatin	Vinorelbine
Treatment duration/ criteria for end of treatment	4 cycles of treatment	4 cycles of treatment	4 cycles of treatment
Need for diagnostics or other tests (i.e. companion diagnostics)	No	No	No
Package size(s)	1mg/ml in a vial of 50 ml	10 mg/ml in a vial of 45 ml	20 mg, 1 capsule

Table 5 Overview of Comparator 2- Neoadjuvant nivolumab combined with platinum-based chemotherapy

Overview of comparator	Nivolumab	Cisplatin	Carboplatin	Vinorelbine
Generic name	Nivolumab "Opdivo"	Cisplatin "Accord"	Carboplatin "Accord"	Vinorelbine "Accord"
ATC code	L01FF01	L01XA01	L01XA02	L01CA04
Mechanism of action	Nivolumab is a human monoclonal antibody that blocks the PD-1 receptor on T-cells. By inhibiting PD-1 interaction with its ligands (PD-L1 and PD-L2), nivolumab restores T-cell activity and enhances the immune system's ability to recognise and destroy tumour cells.	Cisplatin binds directly to DNA, creating cross-links that block replication and transcription, leading to the death of cancer cells.	Carboplatin alters the supercoiled structure of DNA, disrupting replication and inhibiting the growth of cancer cells.	Vinorelbine blocks cancer cell division by disrupting microtubels, which are needed to separate chromosomes. This leads to cell death and slows tumour growth.
Method of administration	Intravenous infusion	Intravenous infusion	Intravenous infusion	orally

Overview of comparator	Nivolumab	Cisplatin	Carboplatin	Vinorelbine
Dosing	360 mg is given on day 1 and repeated every 3 weeks for 3 treatment cycles.	75 mg/m², is given day 1 followed by every 22 days for up to 4 treatment cycles.	900 mg, given day 1 and then at day 22 when a new cycle begins, up to 4 cycles in total.	60 mg/m², given on day 1 and 8 every cycle. Cycle is repeated up to 4 times.
Dosing in the health economic model (including relative dose intensity)	N/A	N/A	N/A	N/A
Should the medicine be administered with other medicines?	Administered together with either cisplatin+ vinorelbine or carboplatin+ vinorelbine.	Administered together with vinorelbine.	Administered with vinorelbine.	Administered together with cisplatin or carboplatin.
Treatment duration/ criteria for end of treatment	Up to 4 cycles of treatment	Up to 4 cycles of treatment	Up to 4 cycles of treatment	Up to 4 cycles of treatment
Need for diagnostics or other tests (i.e. companion diagnostics)	No	No	No	No
Package size(s)	40mg/4ml in a vial	1mg/ml in a vial of 50 ml	10 mg/ml in a vial of 45 ml	20 mg, 1 capsule

Table 6 Overview of Comparator 3 - Adjuvant platinum-based chemotherapy

Overview of comparator	Cisplatin	Carboplatin	Vinorelbine
Generic name	Cisplatin "Accord"	Carboplatin "Accord"	Vinorelbine "Accord"
ATC code	L01XA01	L01XA02	L01CA04

Overview of comparator	Cisplatin	Carboplatin	Vinorelbine
Mechanism of action	Cisplatin binds directly to DNA, creating cross-links that block replication and transcription, leading to the death of cancer cells.	Carboplatin alters the supercoiled structure of DNA, disrupting replication and inhibiting the growth of cancer cells.	Vinorelbine blocks cancer cell division by disrupting microtubules, which are needed to separate chromosomes. This leads to cell death and slows tumour growth.
Method of administration	Intravenous infusion	Intravenous infusion	Orally
Dosing	80 mg/m², is given day 1 followed by every 22 days for 4 treatment cycles [62].	5* (GFR+25 mg), given day 1 and then at day 22 when a new cycle begins, 4 cycles in total [63].	60 mg/m², given on day 1 and 8 every cycle. Cycle is repeated 4 times [62].
Dosing in the health economic model (including relative dose intensity)	N/A	N/A	N/A
Should the medicine be administered with other medicines?	Can be administered together with vinorelbine.	Administered with vinorelbine.	Administered together with cisplatin or carboplatin.
Treatment duration/ criteria for end of treatment	4 cycles of treatment	4 cycles of treatment	4 cycles of treatment
Need for diagnostics or other tests (i.e. companion diagnostics)	No	No	No
Package size(s)	1mg/ml in a vial of 50 ml	10 mg/ml in a vial of 45 ml	20 mg, 1 capsule

3.6 Cost-effectiveness of the comparator(s)

In this assessment, three comparators are included: neoadjuvant PDC, neoadjuvant nivolumab + PDC, and adjuvant PDC, in accordance with Danish clinical practice. Nivolumab combined with PDC has previously been assessed by DMC for the neoadjuvant treatment of NSCLC. PDC is well established in Danish clinical practice for the adjuvant treatment of NSCLC (see section 3.3) and is relatively low in cost compared to durvalumab due to generic competition. Therefore, no additional analysis of these comparators is presented in this application.

3.7 Relevant efficacy outcomes

3.7.1 Definition of efficacy outcomes included in the application

The primary clinical efficacy outcome of the AEGEAN trial was event-free survival (EFS), which is the most relevant outcome for this application in comparing the perioperative approach to adjuvant and neoadjuvant treatment. Data for the EFS interim analysis 2 (IA2) with 25.9 months follow-up (Data cut off [DCO], 10 May 2024) are presented [15]. For neoadjuvant nivolumab + PDC, the CheckMate 816 study, one of the primary outcomes was EFS [9], with data from the 4-year update for EFS presented. For the NATCH study, which compared neoadjuvant PDC with adjuvant PDC, the primary outcomes were disease-free survival (DFS) and OS. The median follow-up was 51 months. The data presented in this application are from the randomised ITT population (N= 624). DFS is considered similar to EFS, and in the indirect comparison, they are treated as equivalent.

For this application, EFS is the most important clinical outcome, used both in the direct comparison and the indirect treatment comparisons (ITCs). Subgroup analysis of EFS in patients with a tumour PD-L1 expression level of in PD-L1 ≥1% is presented from AEGEAN and CheckMate 816, respectively.

An overview of the efficacy outcomes is given in Table 7.

Table 7 Efficacy outcome measures relevant for the application

Outcome measure	Time point*	Definition	How was the measure investigated/method of data collection
EFS AEGEAN trial [15]	Median follow-up was 25.9 months	Defined as the time from randomisation to the first of the following: a) documented local or distant recurrence	Measured in the mITT population using BICR assessment, according to the RECIST v1.1 guidelines. Interim analysis 2, DCO May 10 2024

Outcome measure	Time point*	Definition	How was the measure investigated/method of data collection
		(RECIST v1.1); b) death due to any cause or c) disease progression that precludes surgery, or for patients who do not have surgery for a reason other than progression, disease progression (RECIST v1.1) after the surgery eligibility date, or d) disease progression discovered and reported by the investigator upon attempting surgery that prevents completion of surgery, or for patients who do not complete surgery for a reason other than progression, disease progression (RECIST v1.1) after the surgery date	
EFS CheckMate 816 [64]	Median follow-up of 57.6 months	Defined as the length of time from randomisation to any of the following events: any progression of disease precluding surgery, progression or recurrence of disease after surgery.	Based on BICR assessment per RECIST 1.1.

Outcome measure	Time point*	Definition	How was the measure investigated/method of data collection
DFS NATCH [65]	51 months	Defined as time from random assignment to recurrence for patients who underwent resection, to date of surgery for those with unresectable disease at thoracotomy, to first progression for patients not undergoing surgery, or to death for those who died without relapse – WHO tumour criteria.	According to the intention-to-treat principle, and included all randomized patients, eligible or not

Note: * Time point for data collection used in analysis (follow-up time for time-to-event measures)

Validity of outcomes

According to European Medicines Agency (EMA) guidelines on the evaluation of anticancer medicinal products [66], EFS as a primary or co-primary endpoint is especially accepted in neoadjuvant and adjuvant settings or treatments with potentially curative intent, and when there is a high likelihood of early events. EFS can provide earlier indications of treatment efficacy, especially in settings where long-term survival data may take extended periods to mature [66]. Therefore, when appropriately defined and justified, EFS serves as a meaningful endpoint in the assessment of anticancer therapies.

5. Overview of literature

5.1 Literature used for the clinical assessment

A systematic literature review (SLR) was originally conducted in July 2022 to identify clinical evidence (efficacy and safety) from randomised controlled trials (RCT) that enrolled adults with stage I to III NSCLC who were candidates for surgical resection and had received any or no treatment prior to surgery. Updates to the SLR were conducted in October 2023 and in April 2025 (the SLR is presented in Appendix H).

The SLR identified three trials relevant for the comparators of interest in Denmark:

1. AEGEAN (NCT03800134) for the comparison versus neoadjuvant platinum-based chemotherapy (PDC) (Comparator 1), at IA2 (DCO: May 10, 2024)
2. CheckMate 816 (NCT02998528), at 4-year update, (DBL: February 23, 2024) for the comparison versus neoadjuvant nivolumab+ PDC (Comparator 2).
3. NATCH (NCT00913705) for the comparison versus adjuvant PDC (DBL: March 1, 2009) (Comparator 3)

The literature used for the clinical assessment is presented in Table 9 below.

6. Efficacy

6.1 Efficacy of durvalumab + PDC as neoadjuvant treatment, followed by durvalumab monotherapy as adjuvant treatment compared to neoadjuvant PDC (comparison 1) or neoadjuvant nivolumab + PDC (comparison 2) or adjuvant PDC (comparison 3) for patients with rNSCLC at high risk of recurrence and no EGFR mutations or ALK rearrangement

6.1.1 Relevant studies

As previously described, there are three relevant studies to compare the efficacy of durvalumab + PDC as neoadjuvant treatment followed by durvalumab as adjuvant treatment for adults with rNSCLC at high risk of recurrence and no EGFR mutations or ALK rearrangements. In the absence of head-to-head comparisons, ITCs were required to assess the comparative effectiveness and safety of the perioperative durvalumab regimen in AEGEAN versus key comparators.

1) AEGEAN (versus neoadjuvant PDC)
2) CheckMate 816 (versus neoadjuvant nivolumab + PDC)
3) NATCH (versus adjuvant PDC)

AEGEAN is a pivotal Phase 3, randomised, multi-centre, double-blind, placebo-controlled global trial examining the efficacy and safety of perioperative durvalumab (neoadjuvant durvalumab + PDC followed by adjuvant durvalumab) for the treatment of patients with Stage IIA–IIIB (N2) rNSCLC [16]. The modified ITT (mITT) included 740 participants with documented EGFR mutations or ALK gene rearrangements. Patients received durvalumab + PDC (n=366) or placebo + PDC (n=374), followed by adjuvant durvalumab or placebo. The efficacy outcomes from AEGEAN are based on the most recent DCO, May 10, 2024. The safety analysis set (SAS) included all randomised patients in the global cohort who received at least one dose of study treatment, regardless of EGFR or ALK status.

CheckMate 816 is an open-label, phase 3 trial in patients with stage IB to IIIA rNSCLC examining the efficacy of nivolumab plus platinum-based chemotherapy or platinum-based chemotherapy alone, followed by resection [9, 64]. The 4-year follow-up from DBL February 23, 2024, was used in this application for EFS, with a patient cohort of 358 participants (nivolumab + PDC: n=179, PDC: n=179) [10, 64]. Outcomes in PD-L1 ≥ 1% subgroup are presented with the DBL October 14, 2022.

NATCH was an open-label multicentre randomized phase 3 trial of preoperative (hereafter referred to as neoadjuvant) PDC or adjuvant PDC in patients with early-stage NSCLC [65, 68]. The primary endpoint was DFS. Between April 2000 and March 2007, a total of 624 patients from 42 centres in Spain, Germany, Portugal, Sweden, and

Switzerland were randomly assigned to one of three arms: neoadjuvant PDC, adjuvant PDC or surgery without PDC. The PDC regimen consisted of paclitaxel (Taxol) in combination with carboplatin. The median follow-up was 51 months. Analysis reflects the DBL March 1, 2009 [65].

An overview of the studies relevant for this application is presented in Table 12.

Table 12 Overview of study design for studies included in the comparison

Trial name, NCT-number (reference)	Study design	Study duration	Patient population	Intervention	Comparator	Outcomes and follow-up time
AEGEAN, NCT03800134) [16]	A Phase III, Double-blind, Placebo-controlled, Multi-centre [69]	From date of randomization to 5.5 years after randomization. 		to both the adjuvant and the surgery alone arms and within 3 to 4 weeks after the third chemotherapy cycle for those allocated to the preoperative arm. Follow-up continued beyond 5 years (median 51 months).		Administration of 3 cycles at 21-day intervals.		

6.1.2 Comparability of studies

A comparison of AEGEAN, CheckMate 816, and NATCH was done, as these trials were the basis for the ITCs. In general, the trial designs of AEGEAN, CheckMate 816 and NATCH were similar – all were phase 3, global, multicentre RCTs in rNSCLC.

Differences across the three trials were observed for how these were blinded, type of chemotherapy regimens used, number of chemotherapy cycles in the neoadjuvant phase, the trial setting (neoadjuvant versus perioperative) and the version of TNM classification used in the study. AEGEAN [16] included patients with stage II, IIA, or IIIB (N2 only) as defined by the AJCC 8th edition. CheckMate 816 [9, 71-75] included patients with stage IB (≥4 cm), II, IIIA according to the 7th edition. Patients with T2aN0 (4 cm) (IB in 7th edition) would be included in CheckMate 816 but not AEGEAN, and patients with T4N2 (IIIB in both 7th and 8th edition) would be included in AEGEAN but not CheckMate 816. In NATCH patients with IA stage with tumour size more than 2 cm, IB, II, or T2N1 NSCLC patients were included, which means patients with overall earlier disease-stage than in the other two trials [65].

For a comparison of baseline characteristics, see Table 13.

6.1.2.1 Comparability of patients across studies

The baseline characteristics of patients in the studies included in the comparative analysis of efficacy are presented in Table 13. For AEGEAN the mITT population is presented.

The imbalances in baseline characteristics between AEGEAN [16] and CheckMate 816 [9], as well as potential EMs, included a higher proportion of patients who received cisplatin at baseline (CheckMate 816), a higher proportion of patients with stage IIIA disease (CheckMate 816), a lower proportion of patients with stage IIIB disease (CheckMate 816), a higher proportion of patients enrolled in Asia (CheckMate 816), and a higher proportion of patients with PD-L1 <1% (CheckMate 816).

For NATCH, the ITT population is presented. Only the preoperative and adjuvant chemotherapy (PDC) arms are included in Table 13 as the surgery arm's outcomes were not relevant to AEGEAN in the ITC. The population in NATCH was different compared to AEGEAN, including resectable Stage IB, II, T3N1 NSCLC, as well as Stage IA with a tumour size larger than 2cm. There were no details on PD-L1 inclusion/exclusion. EGFR mutation and ALK translocation status were not part of the inclusion/exclusion criteria.

Note: Characteristics for which there were missing or other responses were histologic classification (0.3% of the patients in the durvalumab group and 1.1% of those in the placebo group had other histologic classification), disease stage (0.3% in the durvalumab group had stage IV disease and 0.3% in the placebo group had stage III [not otherwise specified] disease, as reported on the electronic case-report form), and N2 lymph node station stage (1.6% in the durvalumab group and 3.5% in the placebo group had N2 disease with missing data on single-station vs. multistation classifi cation). [1]Eastern Cooperative Oncology Group (ECOG) performance-status scores range from 0 to 5, with higher scores indicating greater disability.[2] In the AEGEAN trial, race was reported by the patients.[3]This category includes Argentina and Turkey only. [4]in AEGEAN, patients with stage IIA disease to stage IIIB (N2 node stage) disease according to the eighth edition of the AJCC Cancer Staging Manual were enrolled [5] in AEGEAN, all patients had disease that was classified as M0 except for one patient in the durvalumab group who had disease that was classified as M1 (not otherwise specified).[6] in CheckMate 816, the percentages are based on the primary analysis population. The status of programmed death ligand 1 (PD-L1) expres sion was determined with the use of the PD-L1 immunohistochemistry (IHC) 28-8 pharmDx assay (Dako); patients with tumor tissue that could not be assessed for PD-L1 expression (≤10% of all the patients who underwent randomisation) were stratified to the subgroup with a PD-L1 expression level of less than 1% at randomisation. [7] In CheckMate 816, tumour mutational burden was not analysed for patients in China, and these patients were included in the "not reported" category. Source: [9, 16] [65]

6.1.3 Comparability of the study population(s) with Danish patients eligible for treatment

The population in the AEGEAN study aligns with the expected patient population in Denmark. The Danish patient population expected to be treated with durvalumab is, according to the approved indication, adults with rNSCLC at high risk of recurrence and no EGFR mutations or ALK rearrangements. This aligns with the inclusion criteria in the AEGEAN trial.

When comparing the characteristics between AEGEAN and Danish patients, no specific published evidence for the Danish population was identified for this exact setting. Hence, data from the DLCG's yearly report (latest from 2023) was used, which includes an overall description of Danish lung cancer patients[45].

Based on this register data, a comparison was done with AEGEAN and CheckMate 816 (Table 14). Overall, patients diagnosed with lung cancer in Denmark were reported to be older than in AEGEAN [16], CheckMate 816 [9], and NATCH [65], around 72 years [45], whereas AEGEAN, CheckMate 816, and NATCH included patients with a median age of 64-65 years. The gender distribution in Denmark is equal, with 48% men [45], whereas in AEGEAN and CheckMate around 70% were men [9, 16] and in NATCH 86-88% were men [65]. Further squamous histology was seen less prevalent in Danish lung cancer patients, around 19% [45] whereas in the respective study arms from AEGEAN, CheckMate 816, and NATCH an equal distribution (around 50%) for non-squamous and squamous histology was seen at baseline [9, 16]. Lobectomies were the most common surgery performed in AEGEAN [16], CheckMate 816 [9], NATCH [65], and in Danish practice [45]. Besides, in a real-world practice some of rNSCLC may not be operable, while the trials included mostly operable patients.

Table 14 Characteristics in the relevant Danish population and in the health economic model

	Value in Danish population (Lung cancer overall) [45]	Value used in health economic model (reference if relevant)
Age	72 years (median)	N/A
Gender (men)	47,9%	N/A
Histology, squamous NSCLC	19%	N/A
PD-L1 expression <1%	31.8%	N/A
Surgery type, lobectomy	83%	N/A

6.1.4 Efficacy – results per AEGEAN

6.1.4.1 Event-free survival

At the time of the second interim analysis (EFS IA2; DCO 10 May 2022) of AEGEAN, 289 EFS events (using BICR per RECIST v1.1) had occurred in the mITT population (Table 15) [15, 16]. Median follow-up for EFS in censored patients was 25.9 months (range, 0.0 to 58.6). [redacted] HR was 0.69 (95% CI: 0.55, 0.88), representing a 31% overall reduction in the risk of an EFS event [15, 16]. The median EFS was not reached (NR) for the durvalumab arm (95% CI: 42.3 months, NR) and 30.0 months (95% CI: 20.6 months, NR) for the placebo arm [15, 16].

[redacted]

After three months post-randomisation, there was clear and sustained separation of the curves that favoured the durvalumab arm, also reflected in the estimated EFS rates (Table 15) [15].

Table 15 Event-free survival mITT population (EFS IA2 10 May 2024) AEGEAN

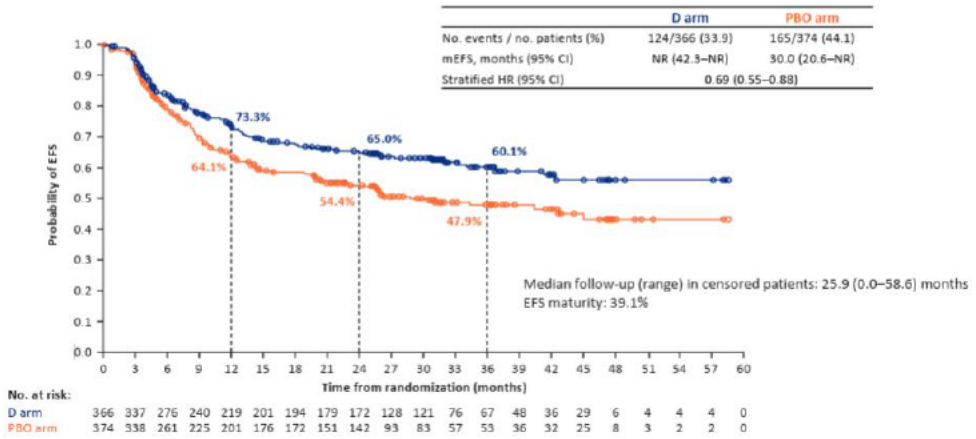
	Durvalumab arm (N = 366)	Placebo arm, PDC neoadjuvant (N = 374)
Events, n (%)[a]	124 (33.9%)	164 (44.1%)
Median EFS, months (95% CI)[e]	NR (42.3, NR)	30.0 (20.6, NR)
HR (95% CI)[c] p-value	0.69 (0.55, 0.88) NR	
Landmark EFS, % (95% CI)[e]		
12 months	73.3 (68.1, 77.7)	64.1 (58.7, 69.0)
24 months	65.0 (59.4, 70.0)	54.4 (48.7, 59.6)
36 months	60.1 (53.9, 65.8)	47.9 (41.8, 53.8)

Notes: DCO: 10th November 2022 (IA1), DCO: 10th May 2024 (IA2). [a]Two missed visit rule applied. [b]New malignancy that is not NSCLC as confirmed by pathology is not considered an EFS event. [c]Calculated using a stratified Cox proportional hazards model adjusted for disease stage and PD-L1 expression status at baseline. An HR <1 favours the durvalumab arm. nr: Not reported. [e]Calculated using the KM technique.

Abbreviations: CI: confidence interval; DCO: data cut-off; EFS: event-free survival; HR: hazard ratio; IA: interim analysis; RECIST: Response Evaluation Criteria in Solid Tumours.

Source: [15-17]

Figure 3 KM curves for event free survival, mITT population (EFS IA2 10 May 2024) AEGEAN



Note: DCO: 10th May 2024. Patients who have not experienced an EFS event at the time of analysis are censored at the time of the last disease assessment. If the event occurs after two or more consecutive missed visits, the patient is censored at the last disease assessment prior to the two missed visits. A new malignancy that is not NSCLC, as confirmed by pathology, is not considered an EFS event.

Source: [15]

6.1.4.2 Overall survival

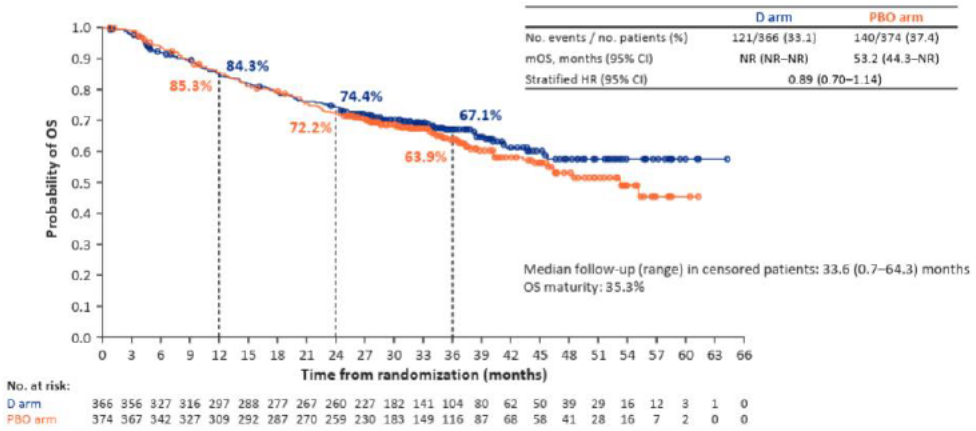
At the time of EFS IA2 (DCO: 10th May 2024), the median duration of OS follow-up in censored patients was 33.6 months (range: 0.7–64.3 months), and OS data had an overall maturity of 35.3% [15]. The median OS was not reached in in the durvalumab arm and was 53.2 months (95% CI: 44.3, NR) in the placebo arm, HR of 0.89 (95% CI: 0.70, 1.14), representing an 11% overall reduction in the risk of death and a trend toward improvement in favour of the durvalumab arm [15]. At EFS IA2, the OS KM curves were similar until approximately 20 months (Figure 4), after which there was a sustained separation that favoured the durvalumab arm [15]. The delayed curve separation arises from the treatment sequence in the placebo arm, where patients first had surgery before starting chemotherapy.

Table 16 Overall survival mITT population (EFS IA2 10 May 2024) AEGEAN

	Durvalumab arm (N = 366)	Placebo arm (N = 374)
Deaths, n (%)	121 (33.1)	140 (37.4)
Median OS, months (95% CI)[a]	NR	53.2 (95% CI: 44.3, NR)
HR (95% CI)[b] p-value	0.89 (0.70, 1.14)	

Note: [a] Calculated using the Kaplan-Meier technique [b]Calculated using a stratified Cox proportional hazards model adjusted for disease stage and PD-L1 expression status at baseline. A HR < 1 favors the durvalumab arm, to be associated with longer OS than placebo arm.

Figure 4 KM curves for overall survival, mITT (EFS IA2 10 May 2024) AEGEAN



Note: DCO: 10th May 2024. OS was defined as the time from the date of randomisation until death due to any cause. Patients who had not experienced an OS event at the time of analysis were censored at the date last known alive.

Source: [15]

6.1.4.3 Lung cancer specific deaths

Death related to lung cancer were reported in [redacted] and [redacted] in the durvalumab and placebo arm, respectively (Table 17). Considering the mean age at inclusion, the death not-related to the disease were most likely resulting from age-related causes.

Table 17 Deaths related to disease, mITT population (EFS IA2 10 May 2024) AEGEAN

Category	Durvalumab arm (N = 366)	Placebo arm (N = 374)
Total number of deaths	121 (33.1)	140 (37.4)
Death related to disease under investigation only[a]	[redacted]	[redacted]

[redacted]

6.1.4.4 Event free survival and overall survival in PD-L1 ≥1% subgroup

At EFS IA2 (DCO: 10th May 2024), 186 EFS events (using BICR per RECIST v1.1) had occurred in the PD-L1 expression ≥1% subgroup population [redacted]). Durvalumab demonstrated a clinically meaningful benefit in EFS, with an HR of 0.71 (95% CI: 0.53, 0.94). After three months post-randomisation, there was a clear and sustained separation in the EFS KM curves that favoured the durvalumab arm, similar to the mITT

population [redacted] This benefit is reflected in the estimated EFS rates at 12 months [redacted] for the durvalumab and placebo arms, respectively), 24 months [redacted] and 36 months ([redacted]) [17].

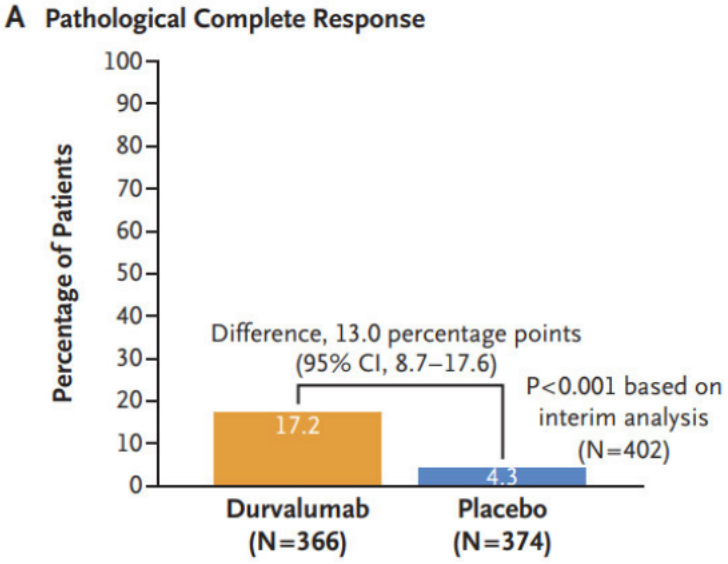
6.1.4.5 Pathological complete response

In the AEGEAN study (EFS IA2 10 May 2024), treatment with durvalumab resulted in a pathological complete response (pCR) rate of 17.2%, compared to 4.3% in the placebo arm, with a difference of 13.0 percentage points (95% CI: 8.7, 17.6). This difference was statistically significant, demonstrating a clinically meaningful improvement in pCR rates in favour of the durvalumab arm [16].

Figure 6 Pathological Complete Response in mITT (DCO, 10 November 2022)



Notes: Pathological complete response was defined as a lack of viable tumor cells after complete evaluation of the resected lung-cancer specimen and all sampled regional lymph nodes.

Abbreviation: CI: Confidence interval; DCO: data cut-off.

6.1.5.2 Event free survival in PD-L1 ≥1% subgroup

With a minimum follow-up of 32.9 months (DBL 14 October 2022), EFS results for the subgroup of patients with tumour PD-L1 expression ≥ 1% are presented in Table 21, and the KM curve in Table 21 [78]. The median EFS was not reached with nivolumab+PDC and 26.71 months (95% CI, 13.4, NR) with PDC alone, HR 0.49 (95% CI 0.29,0.83) [78].

Table 21 Event free surival in patients with tumour PD-L1 ≥ 1% (DBL 14 October 2022) CheckMate 816

	Nivolumab + PDC (N= 81)	PDC (N=86)
Events, n (%)	22 (27.2%)	39 (45.3%)
Median (months)[b] (95% CI)	NR (44.42, NR)	26.71 (13.40, NR)

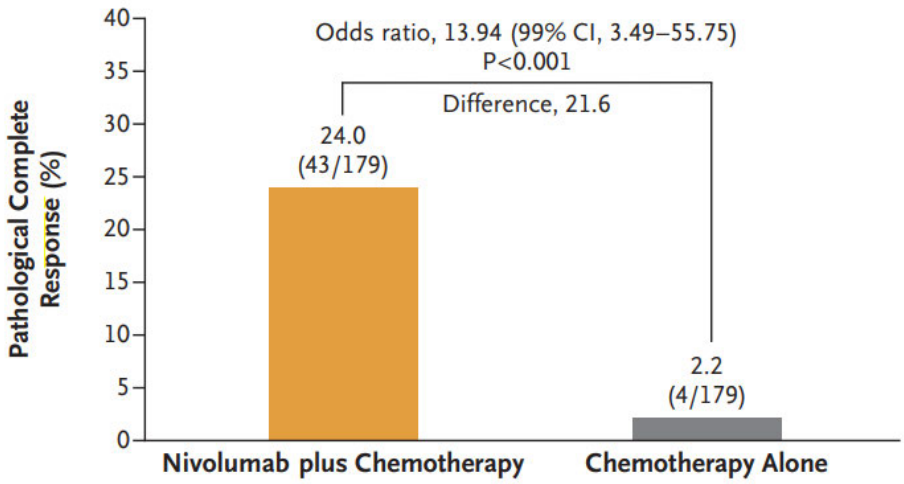
6.1.5.3 Pathological complete response

In the CM816 study, the pCR rate observed in patients receiving nivolumab plus chemotherapy was 24.0%, compared with 2.2% for chemotherapy alone, corresponding to a difference of 21.6 percentage points. The odds ratio was 13.94 (99% CI: 3.49, 55.75), indicating a substantial benefit in pCR for the nivolumab combination over chemotherapy alone [9].

Figure 8 Pathological Complete Response in ITT (DBL, 16 September 2020)



Notes: Pathological complete response was defined as 0% residual viable tumor cells in both primary tumor (lung) and sampled lymph nodes. According to the intention-to-treat principle, patients who did not undergo surgery were counted as not having had a response for the primary analysis. The between-group difference was calculated by means of a stratified Cochran–Mantel–Haenszel method.

Abbreviation: CI: Confidence interval; DBL: Database lock.

6.1.6 Efficacy – results per NATCH

6.1.6.1 Disease-free survival

In the NATCH study, with a median follow up of 51 months, 619 patients were included in the ITT analyses, surgery arm (N=210) preopreative/neoadjuvant PDC + surgery arm (N=199) and the surgery + adjuvant PDC arm (N=210). Summary results for DFS for adjuvant PDC and surgery are presented in Table 22. The adjuvant PDC group had 125 (59.5%) events and surgery group had 132 (62.9%) events (disease progression or death), with no statistically significant differences in DFS with the addition adjuvant PDC to surgery, HR = 0.96 (95% CI, 0.75 to 1.22) p=0.74 [65].

Table 22 Disease-free survival in NATCH

Outcome	Surgery (N=210)	Adjuvant PDC (N=210)
Events	132 (62.9%)	125 (59.5%)
Hazard ratio (95% CI) p-value	0.96 (0.75, 1.22) 0.74

7. Comparative analyses of efficacy

7.1.1 Differences in definitions of outcomes between studies

For the comparison to neoadjuvant PDC, the head-to-head results from AEGEAN were used (see section 6.1.4). In the absence of head-to-head comparisons for neoadjuvant nivolumab + PDC and adjuvant PDC, two ITCs were performed.

Definitions of the time-to-event outcome, which included progression, recurrence, and death (EFS and DFS), in the studies used in the ITC were similar but not identical. All trials reported EFS or DFS as time until progression, recurrence, or death. For the ITCs the endpoints (EFS and DFS) were considered interchangeable, based on the similarity of

their outcome definitions (see Table 7). Also, specific PDC regimes are considered interchangeable.

The ITC did not include pCR between AEGEAN and CheckMate 816. Direct pairwise comparisons of pCR between AEGEAN (durvalumab) and CM816 (nivolumab) are not appropriate without proper statistical adjustment, as differences in study populations, trial designs, and other confounding clinical factors may impact efficacy estimates.

7.1.2 Method of synthesis

Two different methods were used for the indirect comparisons, network meta-analysis (NMA) and a matching-adjusted indirect comparison (MAIC). The ITC methods that were considered were primarily based on those recommended by the National Institute for Health and Care Excellence (NICE) Decision Support Unit (DSU) in Technical Support Documents (TSD) [79]. Given the differences in the patient populations across the trials, a MAIC was considered suitable for the ITCs, matching the AEGEAN mITT population to the populations in CheckMate 816 and NATCH, respectively. A feasibility assessment found that an MAIC was suitable for the ITC between AEGEAN and CheckMate 816, given that they are contemporary clinical studies with similar inclusion and exclusion criteria. However, it was found difficult to match the population of AEGEAN to better fit the population in NATCH, and the need to incorporate comparators for other settings led to the decision to perform the ITC against NATCH using an NMA approach. NMA is a generalisation of standard pairwise meta-analysis that permits the synthesis of relative effect estimates on three or more treatments in a connected network [80, 81].

In conclusion, to compare perioperative durvalumab with adjuvant PDC, an NMA was used, and for the ITC versus neoadjuvant IO + PDC (CheckMate 816), a population-adjusted ITC (pairwise) was chosen to account for differences in stage, PD-L1 expression, region and platinum-chemotherapy at baseline.

[redacted]

7.1.2.1 MAIC versus CheckMate 816

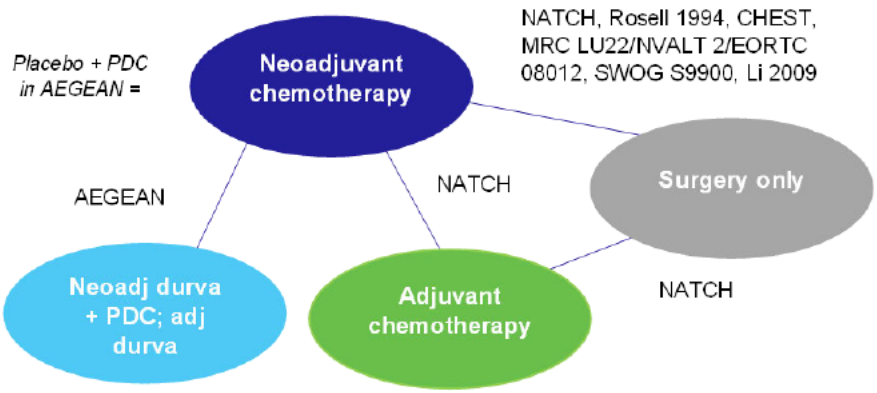
Anchored MAIC analyses were performed to compare the EFS of perioperative durvalumab + neoadjuvant platinum-based chemotherapy from the AEGEAN trial [16] vs neoadjuvant nivolumab + PDC from CheckMate 816 [9, 71-75] (in the AEGEAN mITT population).

The first step was to match the AEGEAN population to the population in CheckMate 816. The following characteristics were considered to be possible effect modifiers: disease stage, PD-L1 expression, region (Asia vs non-Asia), sex, histology, smoking status, and planned platinum chemotherapy. Details on the methodology are provided in C.2.

7.1.2.2 NMA versus adjuvant PDC

The EFS NMA (base case) in the mITT population is shown as a network diagram in Figure 9.

Figure 9 Network diagram of AEGEAN vs adjuvant PDC and surgery for EFS



The data inputs used in the NMA are shown in Table 23. For details on the NMA, please see section C.3.1.

Table 23 Overview of the mITT population NMA: sample size and number of events (overall period and piecewise)

Study	Treatment	Total subjects	Subjects with events	Subjects with event within 3 months	Subjects with event after 3 months
AEGEAN	Durvalumab	366	124 (33.9%)	18 (4.9%)	106 (29.0%)
	Neoadjuvant chemotherapy	374	165 (44.1%)	20 (5.3%)	145 (38.8%)
NATCH	Adjuvant chemotherapy	210	124 (59.0%)	37 (17.6%)	87 (41.4%)
	Neoadjuvant chemotherapy	199	120 (60.3%)	15 (7.5%)	105 (52.8%)
	Surgery	210	133 (63.3%)	30 (14.3%)	103 (49.0%)

Note: The number at risk and number of events in comparator trials were based on pseudo patient-level data generated from digitisation of the EFS KM curves.

7.1.3 Results from the comparative analysis

Tables below report the results of the comparative analysis of EFS for the three relevant comparators to perioperative durvalumab:

1) Direct evidence versus neoadjuvant PDC (AEGEAN) - Table 24
2) Indirect evidence versus neoadjuvant nivolumab + PDC (CheckMate 816) - [redacted] (piecewise MAIC), [redacted] (PD-L1 ≥ 1%)

3) Indirect evidence versus adjuvant PDC (NATCH) - [redacted]

9. Safety

9.1 Safety data from the clinical documentation

In this section, an overview of safety events for AEGEAN (Table 34 and Table 37), CheckMate 816 (Table 35 and Table 38) and NATCH (Table 36) are presented. The adverse events in AEGEAN are presented for the SAS (safety was assessed in all patients who underwent randomisation and received at least one dose of any trial treatment [i.e., durvalumab or chemotherapy] or placebo) and for the overall period (the neoadjuvant, adjuvant and post-surgical periods not separated). The DCO used was 10th May 2024 (IA2) [16] of AEGEAN and the 4-year update for CheckMate 816 DBL 23rd February 2024 [64] and the 5-year update for CheckMate 816 DBL 23rd January 2025 [83].

In NATCH chemotherapy (preoperative/neoadjuvant and adjuvant), paclitaxel (200 mg/m^2 administered intravenously over 3 hours) was followed immediately by carboplatin (at an area under the curve dose of 6.0 mg/mL/min, administered intravenously over a period of 30 to 60 minutes). Treatment was repeated every three weeks for three cycles. Adverse events were reported for subjects who received at least

one cycle of protocol chemotherapy treatment. The median follow-up time was 51 months. Serious adverse events and adverse events for the surgery-only arm were not reported in the NATCH publication [65].

*Adverse events were coded according to the Medical Dictionary for Regulatory Activities, version 27.1, 1 (except surgery-related adverse events used version 25.0), and were graded according to the Common Terminology Criteria for Adverse Events, version 4.0.

†Included are events reported between the first neoadjuvant dose and 30 days after the last neoadjuvant dose.

‡Most frequent (≥15% of patients in any treatment group).

¶The denominators are based on patients who underwent definitive surgery. Included are events reported up to 90 days after definitive surgery. Grade 5 surgery-related adverse events (defined as events that led to death ≤24 hours after the onset of an adverse event) were reported in two patients in the nivolumab plus chemotherapy group and were deemed by the investigator to be unrelated to the trial drugs (one each due to pulmonary embolism and aortic rupture).

10. Documentation of health-related quality of life (HRQoL)

Table 41 below gives an overview of the patient-reported outcome (PRO) from AEGEAN [17] and CheckMate 816 [18].

PRO measures were included as secondary endpoints in the AEGEAN study and assessed using the European Organisation for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire Core 30 (QLQ-C30) and the lung cancer specific module, Quality of Life Questionnaire - Lung Cancer 13 (QLQ-LC13), in the neoadjuvant period [17]. In addition, patient global Impression of severity (PGIS) and the patient reported outcomes version of the common terminology criteria for adverse events (PRO-CTCAE) questionnaires were collected as exploratory endpoints. In this assessment, the EORTC QLQ-C30 and QLQ-LC13 are included.

In CheckMate 816, health-related quality of life (HRQoL) was an exploratory endpoint, measured with the EuroQol 5-Dimension 3-Level (EQ-5D-3L) instrument [18]. Changes from baseline in EQ-5D visual analogue scale (VAS; range 0 to 100) and utility index (UI; range −0.594 to 1) scores during the neoadjuvant period (week 4, week 7, and post-neoadjuvant visit 1) was done [18].

In the NATCH trial health related quality of life was not measured [65].

Table 41 Overview of included HRQoL instruments

Measuring instrument	Source	Utilization
EQ-5D-3L	CheckMate 816	EQ-5D-3L is a generic questionnaire HRQoL. The EQ-5D-3L questionnaire contains a visual analogue scale (EQ-VAS) that provides an aggregate estimate of the patient's self-reported health state on a scale from 0 to 100 (0 and 100 being the worst and best possible health, respectively).
EORTC QLQ-C30	AEGEAN	The EORTC QLQ-C30 is used to evaluate multiple dimensions of cancer patients HRQoL including physical functioning, emotional wellbeing, fatigue, pain, and overall health. It provides a comprehensive profile of

Measuring instrument	Source	Utilization
		functioning and symptom burden across the patient population.
EORTC QLQ-LC13	AEGEAN	The EORTC QLQ-LC13 is a lung cancer-specific instrument used in conjunction with the QLQ-C30. It assesses lung cancer–related symptoms such as coughing, hemoptysis, dyspnoea, and side effects from chemotherapy or radiotherapy, providing disease-specific insights into quality of life.

10.1 Presentation of the health-related quality of life

10.1.1 Study design and measuring instrument

10.1.1.1 EORTC QLQ-C30 AEGEAN

The EORTC QLQ-C30 is a core generic questionnaire designed to measure HRQoL in cancer patients. The questionnaire is composed of 30 items. The "core" instrument is combined with disease specific modules, in this case the lung cancer module (QLQ-LC13).

EORTC QLQ-C30 HRQoL data was collected in the AEGEAN study, with change from baseline [17]. Separate analyses of the change from baseline in EORTC QLQ-C30 (which was collected during both neoadjuvant and adjuvant treatment visits), were planned for the neoadjuvant period, in the mITT population, and for the adjuvant period, in the modified resected set [17]. The EORTC QLQ-C30 data were summarised descriptively with respect to change from baseline and clinically relevant changes (≥10 points from baseline) [17].

Mixed models for repeated measures (MMRM) were used to estimate changes from baseline and difference between treatment arms, by visit and on average during the neoadjuvant period and adjuvant period, with covariate adjustment for baseline score [17].

MMRM analyses were conducted for the following five scales/items: Global Health Score/Quality of life (GHS/QoL), physical functioning, role functioning, fatigue and appetite loss (EORTC QLQ-C30) [17]. Time to Treatment Discontinuation (TTD) in EORTC QLQ-C30 symptoms, functioning and GHS/QoL was also calculated from the adjuvant baseline until the first confirmed meaningful deterioration or death, whichever came first, and compared between treatment arms using a stratified log-rank test adjusted for disease stage and PD-L1 expression status at baseline.

Assessment of differences between treatment arms was performed without adjustment made for multiplicity [17].

10.1.1.2 EORTC QLQ-LC13 AEGEAN

The EORTC developed a questionnaire module for the assessment of HRQoL in lung cancer patients, QLQ-LC13, consisting of 13 items to be used in conjunction with the core questionnaire QLQ-C30. The QLQ-LC14 is a valid and useful tool for assessing disease- and treatment-specific symptoms in lung cancer patients, when combined with the EORTC QLQ-C30. In the AEGEAN study, HRQoL data were collected with the 13-item lung cancer-specific questionnaire module [17].

The EORTC QLQ-LC13 data were summarised descriptively with respect to change from baseline and clinically relevant changes (≥10 points from baseline). MMRM were used to estimate changes from baseline and differences between treatment arms, by visit and on average during the neoadjuvant period and adjuvant period, with covariate adjustment for baseline score [17].

MMRM analyses were conducted for the following three scales/items: dyspnoea, chest pain and cough in the neoadjuvant period only. Assessment of differences between treatment arms was performed without an adjustment made for multiplicity [17].

10.1.1.3 EQ-5D-3L VAS CheckMate 816

HRQoL was evaluated using EQ-5D-3L. A MMRM analysis evaluated longitudinal changes from baseline in EQ-5D visual analogue scale (VAS; range 0 to 100) and utility index (UI; range −0.594 to 1) scores during the neoadjuvant period (week 4, week 7, and post-neoadjuvant visit 1); higher scores reflect better HRQoL [18].

10.1.3.3 EQ-5D-3L VAS CheckMate 816

EQ-5D-3L scores during the neoadjuvant period were generally similar to baseline for both treatment arms; there were no clinically meaningful differences between nivolumab+PDC versus PDC alone Table 48 [18].

In both treatment arms, most patients reported "no problems" for individual EQ-5D-3L dimensions (mobility, self-care, usual activities, pain/discomfort, and anxiety/depression) at baseline and during treatment [18].

Table 48 HRQoL EQ-5D-5L VAS summary statistics

	Nivolumab + PDC	PDC	Nivolumab +PDC vs. PDC Difference (95% CI)
Baseline			
VAS; MID = 7			
Overall	−0.9 (−2.4, 0.7)	−1.5 (−3.1, 0.1)	0.6 (−1.5, 2.7)
Wk 4	−0.4 (−2.1, 1.4)	−1.7 (−3.5, 0.1)	1.3 (−1.0, 3.7)
Wk 7	−1.3 (−3.2, 0.6)	−0.8 (−2.7, 1.2)	−0.6 (−3.2, 2.0)
Post-neoadjuvant visit 1	−0.8 (−2.9, 1.2)	−2.0 (−4.1, 0.2)	1.1 (−1.7, 3.9)

Appendix A. Main characteristics of studies included

A.1 AEGEAN

Table 37 Main characteristics of studies included

Trial name: AEGEAN	**NCT number: NCT03800134**
Objective	To study the efficacy and safety of perioperative durvalumab + neoadjuvant platinum-based chemotherapy for the treatment of patients with resectable Stage IIA–IIIB(N2) NSCLC.
Publications – title, author, journal, year	Perioperative Durvalumab for Resectable Non-Small-Cell Lung Cancer. Heymach JV, et al., N Engl J Med. 2023
Study type and design	A Phase III, double-blinded, placebo-controlled, multi-center clinical trial. Patients were randomly assigned 1:1, in either the intervention arm (durvalumab) or in the comparator arm (placebo). Crossover was not permitted.
Sample size (n)	mITT population: 740 participants (durvalumab: n=366, placebo: n=374)
Main inclusion criteria	Aged ≥18 years at the time of screening

Trial name: AEGEAN	NCT number: NCT03800134
	Newly diagnosed, previously untreated, histologically or cytologically documented resectable (Stage IIA–Stage IIIB[N2]) NSCLC (according to the AJCC TNM lung cancer staging 8th edition), with mediastinal lymph-node staging performed pathologically at the discretion of the investigator Candidate for lobectomy, sleeve resection, or bilobectomy at screening ECOG PS of 0 or 1 at enrolment and randomisation Provision of sufficient tumour biopsy sample for evaluation and confirmation of EGFR and ALK status Documented tumour PD-L1 status prior to randomisation At least one lesion not previously irradiated that qualifies as a Response Evaluation Criteria in Solid Tumours (RECIST v1.1) target lesion at baseline. Tumour assessment by computed tomography or magnetic resonance imaging (MRI) scan must be performed within 28 days prior to randomization.
Main exclusion criteria	Previous exposure to anti–PD-L1, anti–PD-1, or anti–cytotoxic T-lymphocyte antigen 4 antibodies. Uncontrolled intercurrent illness. Specific active or previously documented autoimmune disorders. Sublobar resections as planned surgery at the time of enrollment.
Intervention	Durvalumab + platinum-based chemotherapy was given as neoadjuvant treatment to 366 patients (mITT). Dosage: should be given at four cycles of platinum-based chemotherapy with durvalumab (1500 mg) IV every three weeks, followed by surgery. Following surgery, durvalumab (1500 mg) IV every four weeks for up to 12 cycles.
Comparator(s)	Placebo (placebo+ platinum-based chemotherapy) was given to 374 patients (mITT), of which 3 did not receive neoadjuvant treatment.

Trial name: AEGEAN	NCT number: NCT03800134
	Dosage: Placebo + platinum-based chemotherapy Q3W for 4 cycles, followed by surgery and placebo Q4W for 12 cycles.
Follow-up time	Median follow-up was 25.9 months (range: 0.0 to 58.6 months).
Is the study used in the health economic model?	N/A
Primary, secondary and exploratory endpoints	Primary endpoints: • pCR, measured in the mITT population based on a blinded assessment per central pathology review, according to the methods recommended by IASLC 2020 Secondary endpoints: • EFS, measured in the mITT population using BICR assessment, according to the RECIST v1.1 guidelines. • mPR, measured in the mITT population based on a blinded assessment per central pathology review, according to the methods recommended by IASLC 2020. • DFS, measured in the modified resected population using BICR assessment, according to the RECIST v1.1 guidelines • OS, measured in the mITT population. Other endpoints: • HRQoL, assessed by change from baseline (i.e. last pre-neoadjuvant dose. Endpoints used in the application: • EFS primary, supplementary OS and PFS.
Method of analysis	All efficacy analysis was performed on the mITT population. The Kaplan-Meier survival was used to estimate the primary efficacy endpoint in this application, EFS. The hazard ratios and 95% CI were calculated using a Cox proportional hazards model to compare survival outcomes between the two treatment arms. The same strategy was implemented for OS.

Trial name: AEGEAN	NCT number: NCT03800134
	pCR and mPR were calculated using a stratified Miettinen and Nurminen method. P-value was calculated using a stratified Cochran-Mantel-Haenszel test with a significance boundary <0.001 calculated using a Lan-DeMets alpha spending function with O'Brien Fleming boundary.
Subgroup analyses	N/A
Other relevant information	N/A

A.2 CheckMate-816

Table 63 Main characteristic of studies included

Trial name: CheckMate 816	NCT number: NCT02998528
Objective	The study aims to evaluate the effectiveness and safety of nivolumab in combination with chemotherapy as a neoadjuvant treatment in patients with resectable non-small cell lung cancer.
Publications – title, author, journal, year	Neoadjuvant Nivolumab plus Chemotherapy in Resectable Lung. Forde PM, et al., Cancer. N Engl J Med. 2022. Neoadjuvant nivolumab (NIVO) + chemotherapy (chemo) vs chemo in patients (pts) with resectable NSCLC: 4-year update from CheckMate 816. Jonathan Spicer et al., Journal of Clinical Oncology, meeting abstract: 2024 ASCO Annual meeting ll.
Study type and design	A randomized, open label, Phase 3 Trial. Patients were randomly assigned 1:1. Patients were treated with the intervention nivolumab+ chemotherapy or chemotherapy.
Sample size (n)	mITT population: 358 participants (nivolumab+ chemotherapy: n=179, chemotherapy: n=179)
Main inclusion criteria	Early stage IB-IIIA, operable non-small cell lung cancer, confirmed in tissue.

Trial name: CheckMate 816	NCT number: NCT02998528
	Lung function capacity capable of tolerating the proposed lung surgery. ECOG Performance Status of 0-1. Available tissue of primary lung tumour.
Main exclusion criteria	Presence of locally advanced, inoperable or metastatic disease. Participants with active, known or suspected autoimmune disease. Prior treatment with any drug that targets T cell co-stimulations pathways (such as checkpoint inhibitors).
Intervention	Neoadjuvant treatment: Nivolumab (360 mg) + platinum-based chemotherapy every three weeks for three cycles (n=179, whereof 176 received treatment).
Comparator(s)	Neoadjuvant treatment with platinum-based chemotherapy every three weeks for 3 cycles (n=179, whereof 176 received treatment).
Follow-up time	Median 57.6 months at the 4 year follow up
Is the study used in the health economic model?	N/A
Primary, secondary and exploratory endpoints	Primary endpoints: • EFS, based on BICR assessment per RECIST 1.1. • EFS • pCR, patients not undergoing surgery were included as non-responders for the analysis of pCR, as per EMA guidelines. • pCR

Trial name: CheckMate 816	NCT number: NCT02998528
	Secondary endpoints: • mPR, patients not undergoing surgery were included as non-responders for the analysis of MPR, as per EMA guidelines. • mPR • OS, from randomization to the date of death. • OS • TTDM, defined as the time between the date of randomization and the first date of distant metastasis or the date of death in the absence of distant metastasis. Endpoints included in this application: • EFS, supplementary pCR mPR and OS
Method of analysis	All efficacy analysis was performed on the mITT population. The primary efficacy endpoint, EFS, was estimated using the Kaplan-Meier survival method in this analysis. Survival outcomes between the two treatment arms were compared by calculating the Cox proportional hazard ratios and 95% CI. This same approach was applied to OS.
Subgroup analyses	N/A
Other relevant information	N/A

A.3 NATCH

Table 64 Main characteristic of studies included

Trial name: NATCH	NCT number: NCT00913705
Objective	To compare the effect on disease-free survival of preoperative or adjuvant chemotherapy using paclitaxel-carboplatin with that of observation in patients with early stage NSCLCs. The primary objective of the study was to determine whether preoperative or adjuvant chemotherapy improved disease-free survival in patients with clinically early staged NSCLC. The secondary end points were overall survival and the assessment of chemotherapy adverse events.
Publications – title, author, journal, year	Felip E, et al. Preoperative chemotherapy plus surgery versus surgery plus adjuvant chemotherapy versus surgery alone in early-stage non-small-cell lung cancer. J Clin Oncol. 2010 Jul 1;28(19):3138-45. doi: 10.1200/JCO.2009.27.6204. Epub 2010 Jun 1. PMID: 20516435. [65]
Study type and design	Interventional, phase 3, randomised, parallel assignment, open label
Sample size (n)	Randomised N=624 • Surgery alone n=212 • Preoperative chemotherapy n =201 Adjuvant chemotherapy n=211
Main inclusion criteria	• The patients eligible for the study are those with a diagnosis, histologically or cytologically proven, of NSCLC without metastases at stages IB, IIA, IIB and IIIA (not N2) of the disease. Patients with stage IA and tumor size >2cm will be eligible as well. • Patients aged > 18 years. • Tumor considered resectable by the attending surgeon. • The patient must have an ECOG *2 or Karnofsky >60%. • The patients need to have adequate hematological, renal and hepatic function defined as: Absolute neutrophil counts (ANC*) *1.5 x 109/L Platelet counts *100 x 109/L Total bilirubin *1.25 x upper limit of normal distribution Serum creatinine <120 umol/L (<1.5 mg/dl) Creatinine clearance >60 ml/min

Trial name: NATCH	NCT number: NCT00913705
	• ANC = segmented neutrophils + banded neutrophils • The patients should have recovered from any serious surgical sequellae. • Informed consent must be obtained from the patient in accordance with the requirements of the IRB/EC. • If female, the patient must not be pregnant or breast-feeding. Women of child bearing potential need to have a pregnancy test performed and to take appropriate contraceptive action during the period of the study. • Operability criteria: Lung function test will be performed so as to confirm a predictive postoperative value of FEV-1 >-800 ml, i.e. correct homeostasis. A carbon monoxide diffusion test is to be conducted and, when applicable, repeated following the induction treatment while taking into account the sensitivity of post-chemotherapy pulmonary toxicity detection.
Main exclusion criteria	Patients who have previously been treated with chemotherapy and/or radiotherapy. History of significant cardiovascular disease such as non-controlled hypertension, unstable angina or congestive heart failure even if these are controlled by medication. Documented history of acute myocardial infarction in the previous year, ventricular arrhythmias that required medication or 2nd or 3rd atrial-ventricular blocks. Pre-existing sensory or motor neurotoxicity grade >2 based on the WHO criteria. Active infection or other clinical state that could seriously reduce the patient's capacity to tolerate the treatment protocol, including previous allergic reactions to products containing Cremophor (e.g. cyclosporin or vitamin K). Previous or concomitant malignant tumor (with the exception of in situ cervical carcinoma, baso-cellular carcinoma, squamous cell skin carcinoma or urothelial superficial carcinoma) which are considered potentially curable with oncological treatment and have a disease free survival (DFS) greater than 5 years EXCEPTING breast cancer, melanoma and hypernephroma Marked psychoses or senility
Intervention	1. : Neoadjuvant chemotherapy (taxol and carboplatin)

Trial name: NATCH	NCT number: NCT00913705
	Taxol: 200mg/m2 infusion over 3 hours; Carboplatin: AUC= 6 at the end of the Taxol infusion. Administration of 3 cycles at 21-day intervals. Prior to surgery.
Comparator(s)	2. : Adjuvant chemotherapy (taxol and carboplatin) Taxol: 200mg/m2 infusion over 3 hours; Carboplatin: AUC= 6 at the end of the Taxol infusion. Administration of 3 cycles at 21 days interval. Post-surgery 3. Surgery
Follow-up time	5 years, median 51 months in the analysis
Is the study used in the health economic model?	No
Primary, secondary and exploratory endpoints	Primary: • DFS: defined as the length of time from the date of diagnosis to the date of the first documented progression of disease • OS: defined as the length of time from either the date of diagnosis or the start of the treatment that patients diagnosed with the disease are still alive. Secondary • Occurrence and severity of adverse events
Method of analysis	All analyses were performed according to the intention-to-treat principle and included all randomized patients, eligible or not. Disease-free survival and overall survival curves were constructed by the Kaplan-Meier method and compared with the use of the log-rank test and the Cox proportional hazards model. All reported P values are two-sided. Analysis reflects the database as of March 1, 2009.

Trial name: NATCH	NCT number: NCT00913705
	Chemotherapy adverse events were summarized for all patients who received at least one cycle of the assigned chemotherapy treatment. All statistical calculations were performed using STATA(version 10.0; STATA, College Station, TX).
Subgroup analyses	On Age (over 65, 65 and younger), gender (male, female), ECOG PS (0, 1-2,), pretreatment clinical stage (stage I, Stage II-T3N1), surgery (lobectomy/bilobectomy, pneumonectomy)
Other relevant information	NA

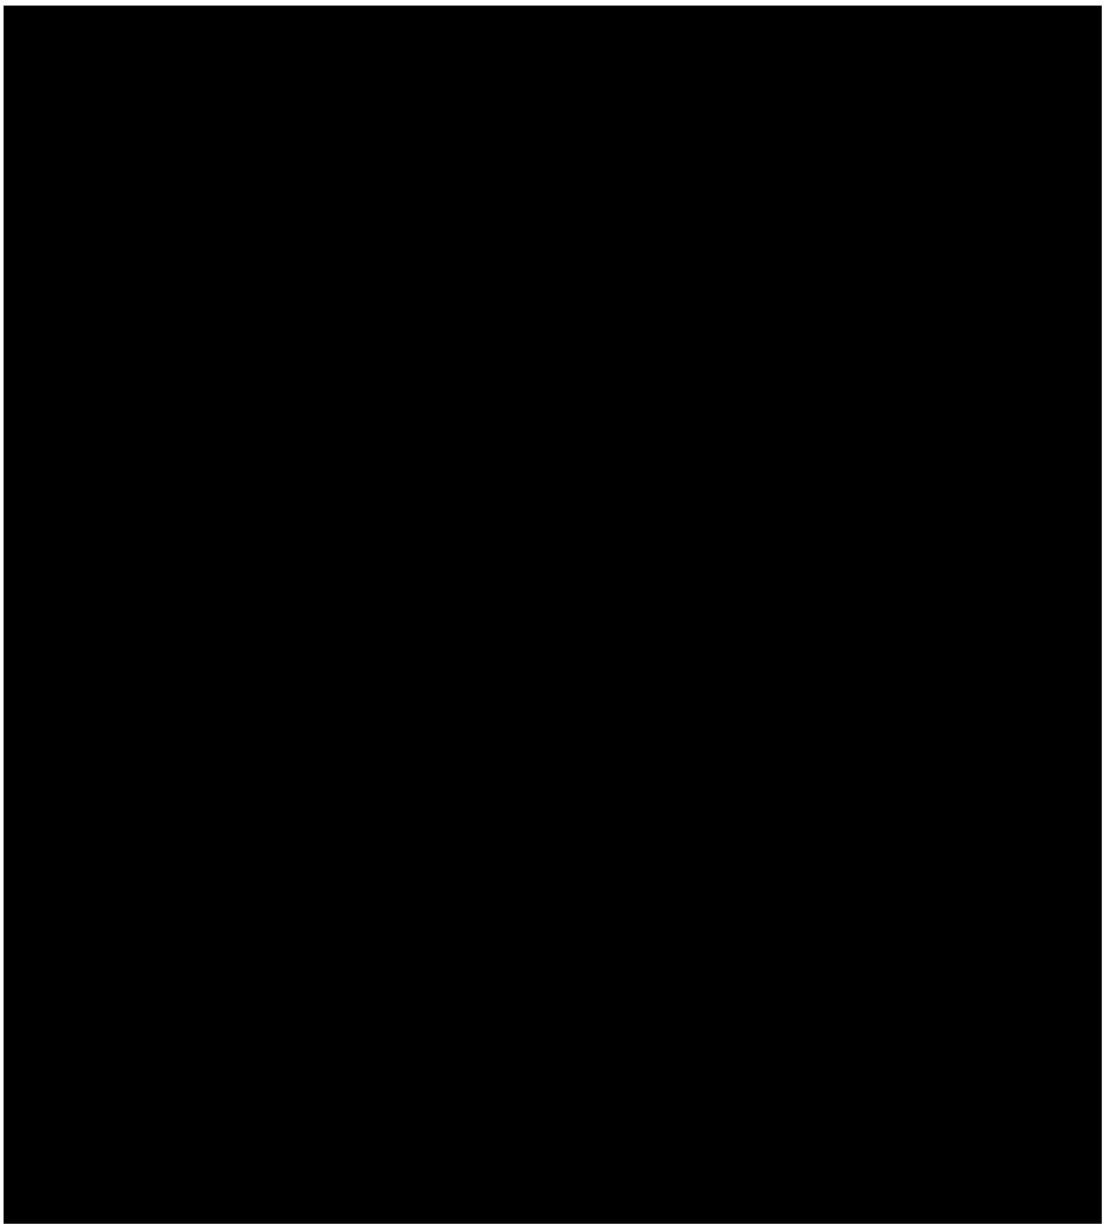
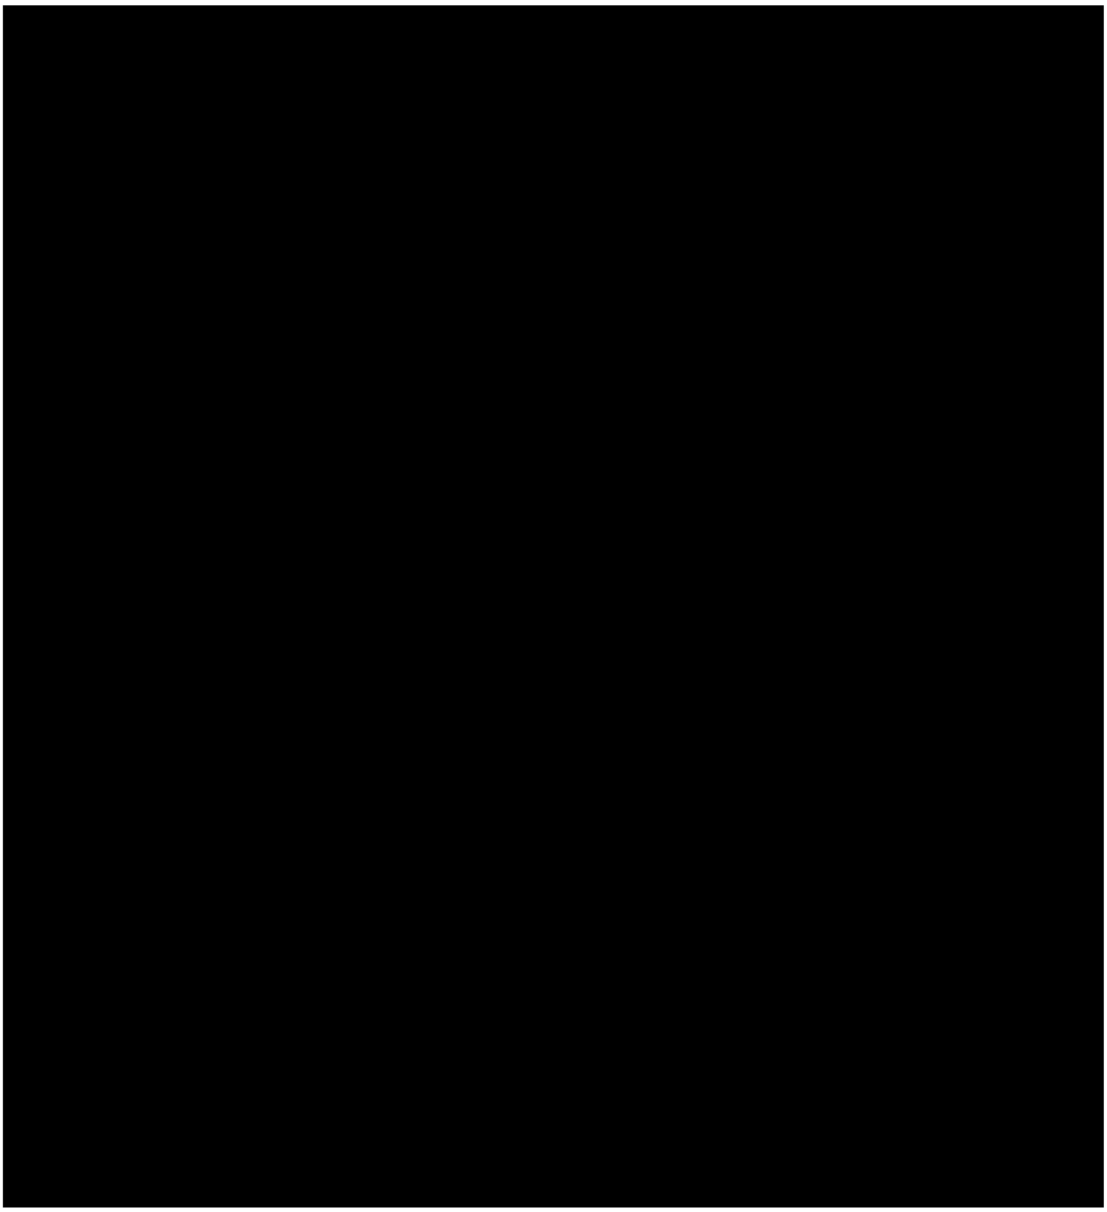
Appendix C. Comparative analysis of efficacy

C.1 Assessment of the proportional hazard assumption



[redacted]

[redacted]



C.2 Matching adjusted indirect comparison

All MAIC analyses were conducted using R version 4.1.0 within the R Studio environment. Packages used included maic (v 0.1.4), survival (v 3.4.0) and survminer (0.4.9).

C.2.1 Matching adjusted indirect comparison versus neoadjuvant novilumab + PDC

The first step in conducting the MAIC involved deriving weights such that the average baseline characteristics in AEGEAN (post-weighting) [16] matched the published aggregate characteristics of the comparator population. For this, a propensity score-type logistic regression equation to estimate weights was used. Specifically, weights were estimated by the odds of being enrolled in the target population (i.e., CheckMate 816) vs AEGEAN, which was calculated as $w_i = exp(\alpha + x_i'\beta)$ where x_i' was the vector of baseline variables that were included for weighting. The β coefficients were determined by the method of moments because only aggregate data for the x_i''s were available for the comparator trial populations, as described in Signorovitch *et al.* [87]. Patients who had missing values for any of the variables included in the MAIC were excluded from the analysis. Once the coefficients were estimated, the equation was applied to the patients from AEGEAN [16] to calculate the individual patient weights.

Next, the distribution of weights was assessed to identify any overly influential observations. The effective sample size (ESS) was calculated by $(\sum w_i)^2/(\sum w_i^2)$. If the populations were perfectly balanced before adjustment, all AEGEAN patients would have $w_i = 1$, and the ESS would equal the original size in AEGEAN's population. Adjustments for population differences assigned patients uneven weights, leading to the inevitable loss of ESS. A low ESS indicates an irregular distribution of weights across patients, meaning that only a small fraction of patients drives the treatment effect in the weighted population [82].

Based on the individual patient weights for the AEGEAN population [16], the (weighted) EFS HRs for perioperative durvalumab + neoadjuvant platinum-based chemotherapy vs perioperative placebo + neoadjuvant platinum-based chemotherapy were derived from weighted Cox PH models. As the weights were derived from the data, robust sandwich estimators were used to compute the standard error (SE) of the weighted logHR in AEGEAN, as recommended in NICE Decision Support Unit (DSU) Technical Support Document (TSD) 18 [88].

The anchored indirect comparison of perioperative durvalumab vs a comparator treatment X was then calculated on the log-scale, using the weighted AEGEAN EFS HR and the EFS HR reported from the comparator trial (both HRs vs the common comparator), in accordance with Bucher et al.[89]:

$$\log HR_{\text{Peri.D } vs.\text{X}} = \log HR^{AEGEAN}_{\text{Peri.D } vs.\text{PDC}} - \log HR^{Comparator\ trial}_{X\ vs.PDC}$$

$$\text{SE}(\log HR_{\text{Peri.D } vs.\text{X}}) = \sqrt{\left(SE\left(\log HR^{AEGEAN}_{\text{Peri.D } vs.\text{PDC}}\right)\right)^2 + \left(SE\left(\log HR^{Comparator\ trial}_{X\ vs.\ PDC}\right)\right)^2}.$$

The output from the indirect comparisons included the EFS HR and 95% CI for the comparison of perioperative durvalumab vs comparator treatment X. In the MAICs, this HR provided an estimate of the relative effect on EFS of perioperative durvalumab vs comparator treatment X in a population matching the characteristics of the comparator trial population. Anchored indirect comparisons using the unweighted HR from AEGEAN were also conducted.

In accordance with NICE DSU TSD 18 [88], anchored MAICs are considered to be warranted when there are imbalances in baseline characteristics that are considered to be possible EMs. The following characteristics were considered to be possible EMs: disease stage, PD-L1 expression, region (Asia vs non-Asia), sex, histology, smoking status, and planned platinum chemotherapy.

In the base case analysis (Scenario 1), all possible EMs were included in the weighting, regardless of whether imbalances exist between trials in these baseline characteristics, as per recommendation 4 in NICE DSU TSD 18 [88]. An additional analysis (Scenario 2) was also conducted to explore the impact on results of only weighting for those characteristics that were imbalanced (≥5% difference) between trials [82].

The list of characteristics included in the weighting in each scenario for each of the two comparisons is shown in Table 68.

Table 68 Scenarios explored for weighting in the MAIC vs CheckMate (AEGEAN mITT population)

Scenario	Variables for weighting	Rationale
1 Base case	Stage (IIIB vs other) Stage (IIIA vs other) PD-L1 (<50% vs ≥50%) PD-L1(<1% vs ≥1%) Histology (squamous vs non-squamous) Region (Asia vs non-Asia) Sex (male vs female) Smoking status (never vs ever/current) Planned platinum chemotherapy (cisplatin vs carboplatin)	Includes all possible EMs
2	Stage (IIIB vs other) Stage (IIIA vs other) PD-L1 (<50% vs ≥50%) PD-L1(<1% vs ≥1%) Region (Asia vs non-Asia) Planned platinum chemotherapy (cisplatin vs carboplatin)	Includes possible EMs with imbalance (≥5%) between trials at baseline

Source: [82]

The summary of event numbers, and the HRs, for AEGEAN (before weighting) and CheckMate 816 are shown in Table 69 and Table 70, respectively.

Table 69 Trial summaries of EFS in AEGEAN and CheckMate 816

Arm	Trial	N	Events	Maturity
Durvalumab + PDC	AEGEAN	366	124	34%
Placebo + PDC	AEGEAN	374	165	44%
Nivolumab + PDC	CheckMate 816	179	75	42%
PDC	CheckMate 816	179	97	54%

Note: AEGEAN EFS IA2 DCO date: 10th May 2024; CheckMate 816: 4-year update DBL date: 23rd February 2024

Abbreviation: PDC: Platinum based doublet chemotherapy

Source: [16, 64]

Table 70 Pre-weighting EFS HRs (vs PDC ± placebo) from AEGEAN and CheckMate 816 (4-year update)

Arm	HR	LCL (95%)	UCL (95%)	Source
Durvalumab + PDC	0.70	0.56	0.89	AEGEAN EFS IA2 (unstratified Cox regression model) DCO date: 10 May 2024 [16]
Nivolumab + PDC	0.66	0.49	0.90	CheckMate 816 4-year update [64]

Abbreviations: DCO, data cutoff; HR, hazard ratio; LCL, lower confidence limit; PDC, platinum-doublet chemotherapy; UCL, upper confidence limit

A comparison of baseline characteristics between the two studies (overall trial, i.e., both arms) before and after weighting is shown in [redacted] (weighting in Scenario 1) and [redacted] (weighting in Scenario 2).

As described in the imbalances in baseline characteristics between AEGEAN[16] and CheckMate 816, [9, 71-75] including:

- The proportion who received cisplatin at baseline (higher in CheckMate 816 [9, 71-75])
- The proportion with stage IIIA at baseline (higher in CheckMate 816 [9, 71-75])
- The proportion with stage IIIB at baseline (lower in CheckMate 816 [9, 71-75])
- The proportion of patients enrolled in Asia (region) (higher in CheckMate 816 [9, 71-75])
- The proportion with PD-L1 <1% (higher in CheckMate 816[9, 71-75])

Each of these characteristics is considered to be a possible EM.

C.3 Network meta analysis

The NMA was conducted in a Bayesian framework, using Monte Carlo Markov Chain simulation methods, and using R version 4.0.2 [88] with the following packages: Rstan (v 2.19.3), multinma (v 0.5.1), and survival (v 3.1.12). The models were run with four chains of 10,000 iterations, of which every second iteration was kept; 5,000 were burn-in iterations (i.e., thinning = 2) to generate the posteriors for the defined parameters. Convergence of the chains was assessed using the Rhat statistic [89].

Since EFS is a time-to-event outcome, the log HRs were analysed using a normal likelihood and identity link (Program 7 of NICE DSU TSD 2) [90].

Non-informative normal (0, 1002) priors were assigned to the treatment effect parameters. Both fixed- and random-effects models were conducted, but there were limited data to estimate between-study heterogeneity for random-effects models, so informative priors based on a log-normal distribution ('subjective outcomes (various)' prior, log-normal ~ (-2.93, 1.582)) were used for random-effects models based on Turner et al [91].

Whereas a fixed-effect model assumes there is a single 'true' effect size underlying the trials informing a treatment comparison (i.e., that differences between studies are purely due to chance variation), random-effects models assume studies informing a treatment comparison are estimating 'similar' effects, but there are differences beyond just chance variation (i.e., total variation = chance differences + between-study heterogeneity). 'Similar' in this case means the effect sizes are coming from a (normal) distribution of effect sizes. Random-effect models are more plausible than fixed-effect models, but there is usually very limited information with which to estimate between-study heterogeneity (as is considered the case here). Given that heterogeneity was identified in the feasibility assessment, the random-effects model was preferred.

When both fixed- and random-effects models were fitted to the data, their deviance information criteria (DIC) were derived. Lower values represent the more parsimonious model, and differences of 3 points were considered meaningful [92]. The model goodness-of-fit was assessed by comparing the posterior mean residual deviance to the number of data points in the network [92]. The number of data points was calculated as the sum of arms across studies reporting arm-level data and the sum of studies reporting contrast-based data. Model fit was considered good if the posterior mean residual deviance was similar to the number of data points [93].

C.3.1 NMA versus adjuvant PDC

EFS HR data were analysed using NMA for the mITT and N2 population of AEGEAN [90, 91]. [redacted] The NMA was conducted in a Bayesian framework, using Monte Carlo Markov Chain simulation methods, and using R version 4.0.2 [92] with the following packages: Rstan (v 2.19.3), multinma (v 0.5.1), and survival (v 3.1.12). The models were run with four chains of 10,000 iterations, of which every second iteration was kept; 5,000 were burn-in iterations (i.e., thinning = 2) to generate the posteriors for the defined parameters. Convergence of the chains was assessed using the Rhat statistic [93].

Since EFS is a time-to-event outcome, the log HRs were analysed using a normal likelihood and identity link (Program 7 of NICE DSU TSD 2) [94].

Non-informative normal $(0, 100^2)$ priors were assigned to the treatment effect parameters. Both fixed- and random-effects models were conducted, but there were limited data to estimate between-study heterogeneity for random-effects models, so informative priors based on a log-normal distribution ('subjective outcomes (various)' prior, log-normal ~ $(-2.93, 1.58^2)$) were used for random-effects models based on Turner et al.[95]

Whereas a fixed-effect model assumes there is a single 'true' effect size underlying the trials informing a treatment comparison (i.e., that differences between studies are purely due to chance variation), random-effects models assume studies informing a treatment comparison are estimating 'similar' effects, but there are differences beyond just chance variation (i.e., total variation = chance differences + between-study heterogeneity). 'Similar' in this case means the effect sizes are coming from a (normal) distribution of effect sizes. Random-effect models are more plausible than fixed-effect models, but there is usually very limited information with which to estimate between-study heterogeneity (as is considered the case here). Given the level of heterogeneity identified in the feasibility assessment, the random-effects model was preferred.

When both fixed- and random-effects models were fitted to the data, their deviance information criteria (DIC) were derived. Lower values represent the more parsimonious model, and differences of 3 points were considered meaningful [96]. The model goodness-of-fit was assessed by comparing the posterior mean residual deviance to the number of data points in the network [96]. The number of data points was calculated as

the sum of arms across studies reporting arm-level data, and the sum of studies reporting contrast-based data. Model fit was considered good if the posterior mean residual deviance was similar to the number of data points.

Appendix H. Literature searches for the clinical assessment

H.1 Efficacy and safety of the intervention and comparator(s)

The objective of conducting a *de novo* SLR was to identify the clinical efficacy and safety of durvalumab and relevant comparators for the treatment of stage I–III NSCLC in patients who are candidates for surgical resection.

The SLR was performed in accordance with a pre-specified protocol. This involved searching electronic databases, hand-searching of key conference proceedings from the last two years, and hand-searching of ClinicalTrials.gov, databases, and the bibliographies of any relevant SLRs (network) or meta-analyses ([N]MAs).

The original search for the SLR was conducted in Embase, MEDLINE, and CENTRAL, including Cochrane Database of Systematic Reviews (CDSR) on the 27th of July 2022, later updated on the 30th of October 2023 (Table 67). For the update, no date restrictions were imposed; instead, the results of the updated searches were de-duplicated against those of the original searches. The Database of Abstracts of Reviews of Effects (DARE) via the University of York CRD platform was not updated, as the database had not been updated since 2016.

An additional literature search was conducted on the 25th April 2025 in MEDLINE only using PubMed (Table 77) to capture any major updates compared to the latest update in 2023 using the same search terms.

As the SLR was conducted to explore comparative clinical evidence more broadly, the SLR was subsequently adapted to the Danish context, in line with the DMC guidelines, which require local alignment when a global SLR is used. The following sections present the original and updated SLR methodology and the Danish adaptation to local context and results.

Table 77 Bibliographic databases included in the literature search

Database	Platform/source	Relevant period for the search	Date of search completion

	PubMed	October 14 2023 - April 25 2025	25.04.2025

Database	Platform/source	Relevant period for the search	Date of search completion
CENTRAL	The Cochrane Library, the Wiley Online	No restriction No restriction	27.07.2022 30.10.2023
DARE	York CRD platform	No restriction	27.07.2022

ClinicalTrials.gov and the World Health Organisation (WHO) International Clinical Trials Registry Platform (ICTRP) were searched (in the original SLR the searches were done on 14th October 2022 and in the updated SLR, on 20th November 2023) using the advanced search function to ensure that all relevant studies were identified. Search terms for each of these sources were devised based on the terms used for the electronic database searches and the specific requirements/format of each search platform. Searches of the ICTRP were date-limited to the 1st of January 2022, and de-duplicated against the results of the original SLR, and searches of ClinicalTrials.gov were date-limited to the date of the search conducted in the original SLR.

Conference proceedings for the last two years (i.e. 2020–2022 in the original SLR and 2023 for the updated SLR from the following congresses were hand-searched to identify any relevant abstracts for inclusion. Where possible, the same search terms and strategy were used for the SLR update as for the original SLR. However, where there were changes in the availability of topics and formatting for some conferences, these strategies were updated as required. ASCO Virtual Plenary Sessions were not available at the time of the original SLR, and so were only searched in the update.

H.1.2 Systematic selection of studies

The study eligibility criteria were developed using the population, intervention, comparator, outcomes, study design (PICOs) framework, and are shown in Table 85 for the original SLR and the SLR updates. As the global SLRs did not restrict studies based on intervention or comparator, the relevant PICOs in Denmark of interest were those that might represent potential comparators to perioperative durvalumab in adults with rNSCLC with high risk of recurrence and no EGFR mutations or ALK rearrangements.

In accordance with DMC guidelines, the PICO from the global SLR was adjusted to the reflect the Danish setting, where neoadjuvant nivolumab+PDC is the SoC for patients with PD-L1 ≥1% tumor expression and PDC alone is SoC in the adjuvant setting. In addition, reporting of HR for EFS was important to include for the ITC for relative efficacy estimation (Table 85).

Table 85 Inclusion and exclusion criteria used for assessment of studies

Clinical effectiveness	Inclusion criteria	Exclusion criteria	Changes, local adaption
Population	Adult patients (≥18 years old) with stage I–III NSCLC who are candidates for surgical resection of the primary NSCLC	Patients without NSCLC Patients with stage IV NSCLC or metastatic NSCLC Patients with stage I–III NSCLC who are not candidates for surgical resection of the primary NSCLC (i.e. stage I–III unresectable NSCLC) Children or adolescents (<18 years old)	Adults (≥18 years old) with rNSCLC at high risk of recurrence and no EGFR mutations or ALK re-arrangements
Intervention	Any or no treatment for stage I–III NSCLC prior to surgical resection of the primary NSCLC	No planned surgical resection of primary NSCLC	Perioperative durvalumab and Danish SoC consisting of neoadjuvant nivolumab+PDC and adjuvant PDC
Comparators	Any or none*	Any or none*	Danish SoC consisting of neoadjuvant nivolumab + PDC and adjuvant PDC
Outcomes	Efficacy outcomes: EFS[a], DFS[a], OS, major pathological response, PCr, PFS[a], RFS[a], Recurrence rates and type Safety outcomes HRQoL outcomes	Studies not reporting relevant outcomes Studies reporting relevant outcomes, but in a mixed population (e.g. patients with stage I–III resectable and unresectable NSCLC) where	Reporting of HR for EFS for relative efficacy

		outcomes are not reported separately for the stage I–III resectable NSCLC population	
Study design/publication type	RCTs Non-RCTs† SLR/(N)MAs were considered relevant at the title/abstract review stage and hand searched for relevant primary studies, but were excluded during the full-text review stage unless they themselves present original research. In the original SLR and SLR update the most stringent record screening process as recommended by Cochrane was followed. The process was as follows:

Each title and abstract were reviewed against the inclusion/exclusion criteria by two independent systematic reviewers. Where the applicability of the inclusion criteria was unclear, the article was included at this stage to ensure that all potentially relevant studies were captured. The independent reviewers then compared their results, and any disagreements were resolved by discussion until a consensus was reached. If necessary, a third independent reviewer was enlisted to arbitrate the final decision.

Each full-text article was then reviewed against the inclusion/exclusion criteria by two independent systematic reviewers, who came to a consensus on the included articles. In

cases where it was unclear whether the article met the inclusion criteria, the article was excluded at this stage to ensure that only relevant articles were ultimately included in the systematic review. The results of the two reviewers were then compared, and any disagreements were resolved by discussion until a consensus was reached. If necessary, a third reviewer was enlisted to arbitrate the final decision.

All publications ultimately included in the SLR were reviewed, and those reporting on the same study were grouped. At subsequent stages of the review (data extraction, quality assessment and write-up), each study was considered as a single unit.

The primary publication for a study was regarded as the earliest journal article which reported outcomes of interest for the study. Secondary publications were considered as any subsequent publications on the study, such as conference abstracts and clinical trial records, which reported outcomes of interest.

A larger-than-anticipated number of records were identified as eligible for inclusion in the review at the time of the original SLR. To manage the scope of the SLR and prioritise the highest-quality and most relevant identified studies, two evidence prioritisation plans were adopted, moving into the extraction phase of the review (for both the original SLR and SLR update). These approaches were as follows:

- Any study design other than an RCT was deprioritised from extraction. This prioritised data from the highest quality study designs
- Studies which compared surgery alone (i.e. had no neoadjuvant or adjuvant treatment) were deprioritised from extraction as being of less relevance to the ITC feasibility assessment. For example, studies were identified that compared different types of surgical resection, which is not considered relevant for the ITC feasibility assessment

Throughout the title/abstract and full-text review stages of the SLR, all identified publications which were deemed relevant for inclusion against the eligibility criteria were formally reported in the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). The evidence prioritisation strategy was enacted, moving into the data extraction phase, and therefore only impacted the number of publications which ultimately underwent full data extraction.

Key studies identified in the original SLR and updated reporting on IO therapies (i.e. atezolizumab, pembrolizumab, nivolumab or durvalumab) included four studies examining neoadjuvant IO (CheckMate 816, NeoCOAST, NEOpredict, NEOSTAR) [9, 97-100], two studies examining neoadjuvant and adjuvant IO (Altorki 2021, NADIM II) [101, 102], and two studies examining adjuvant chemotherapy (Chen 2013, NATCH and Peng [65, 103, 104]). CheckMate 816 was the only phase III trial identified in the original SLR assessing an IO regimen and the SLR update identified additional publications for this trial.

The latest updated search from April 25, 2025, yielded 237 results that were screened on title only, of these 14 articles were selected for abstract review. Following this, eight articles were assessed in full-text review, and finally, one of the studies was included to

evaluate the clinical efficacy and safety of durvalumab and potentially relevant comparators.

All studies identified through the original and updated SLRs were assessed against the Danish PICO to identify the publication and trials relevant for assessing the relative efficacy for perioperative durvalumab versus Danish SoC.

The PRISMA diagram outlining the flow of records through the original SLR is presented in Figure 16; the total number of records and unique studies identified across the original SLR. The PRISMA diagram for the SLR update is shown in Figure 17, and lastly the PRISMA diagram from the latest search in Figure 18.

Figure 16 PRISMA flow diagram for studies identified in the original SLR, 27th July 2022, with Danish adaptation

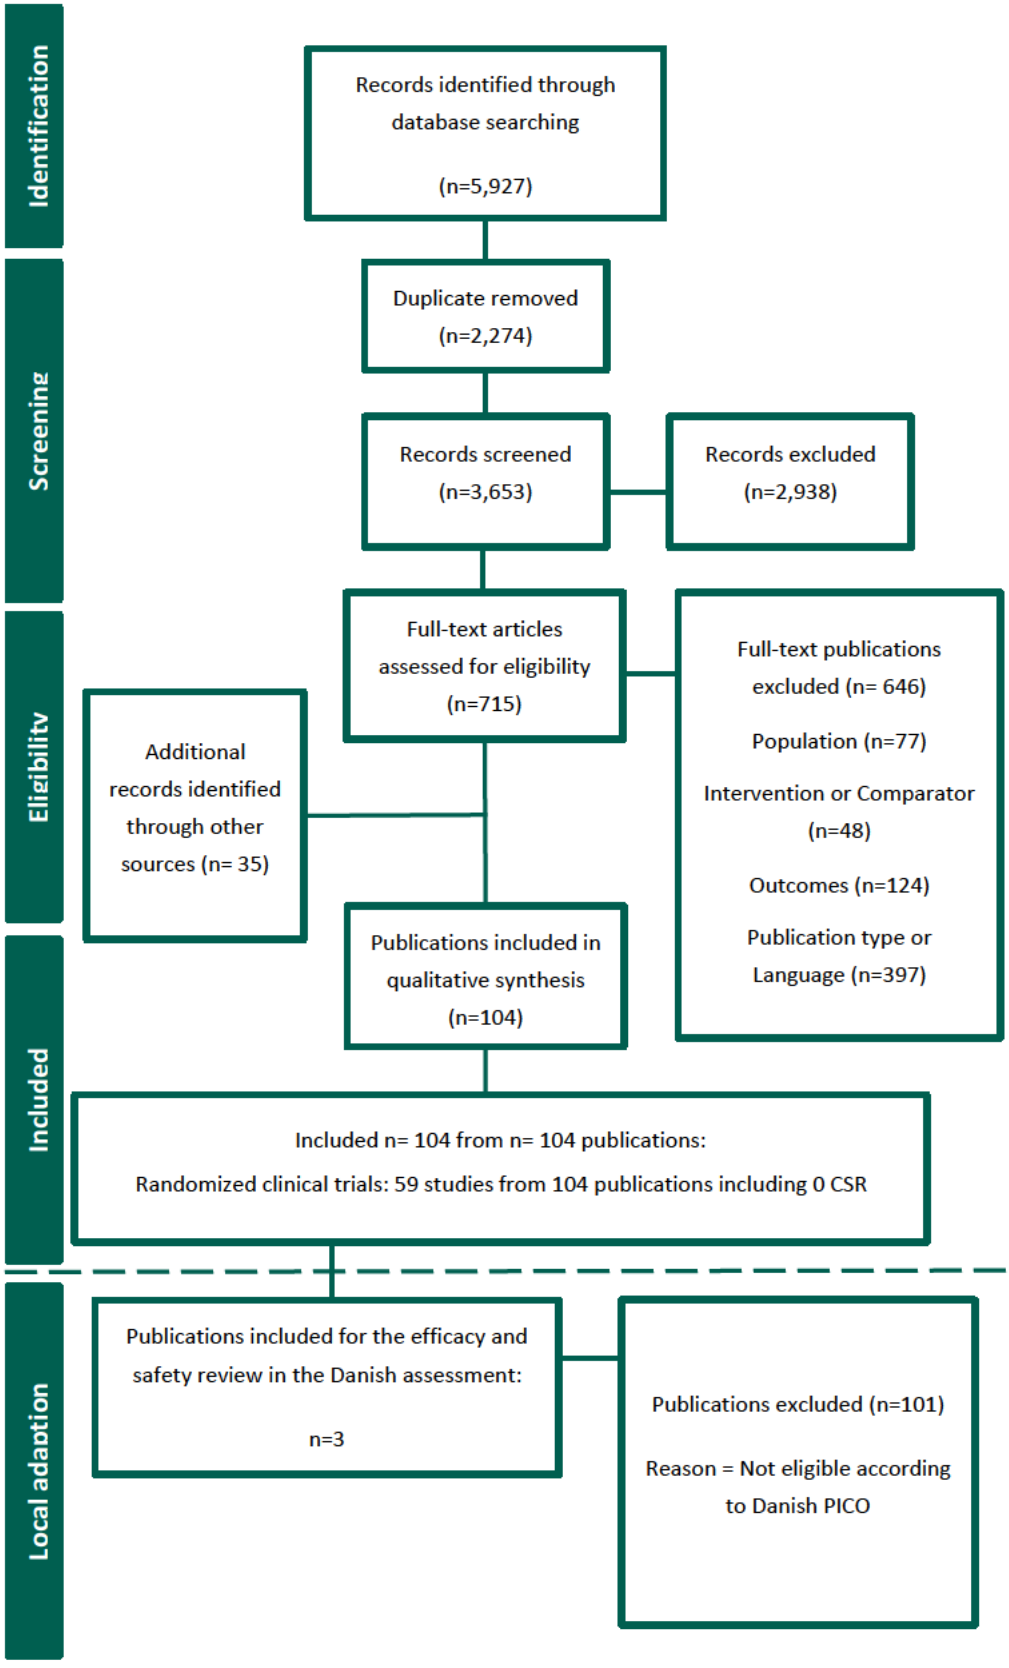

Figure 17 PRISMA flow diagram for studies identified in the updated SLR, 30 October 2023

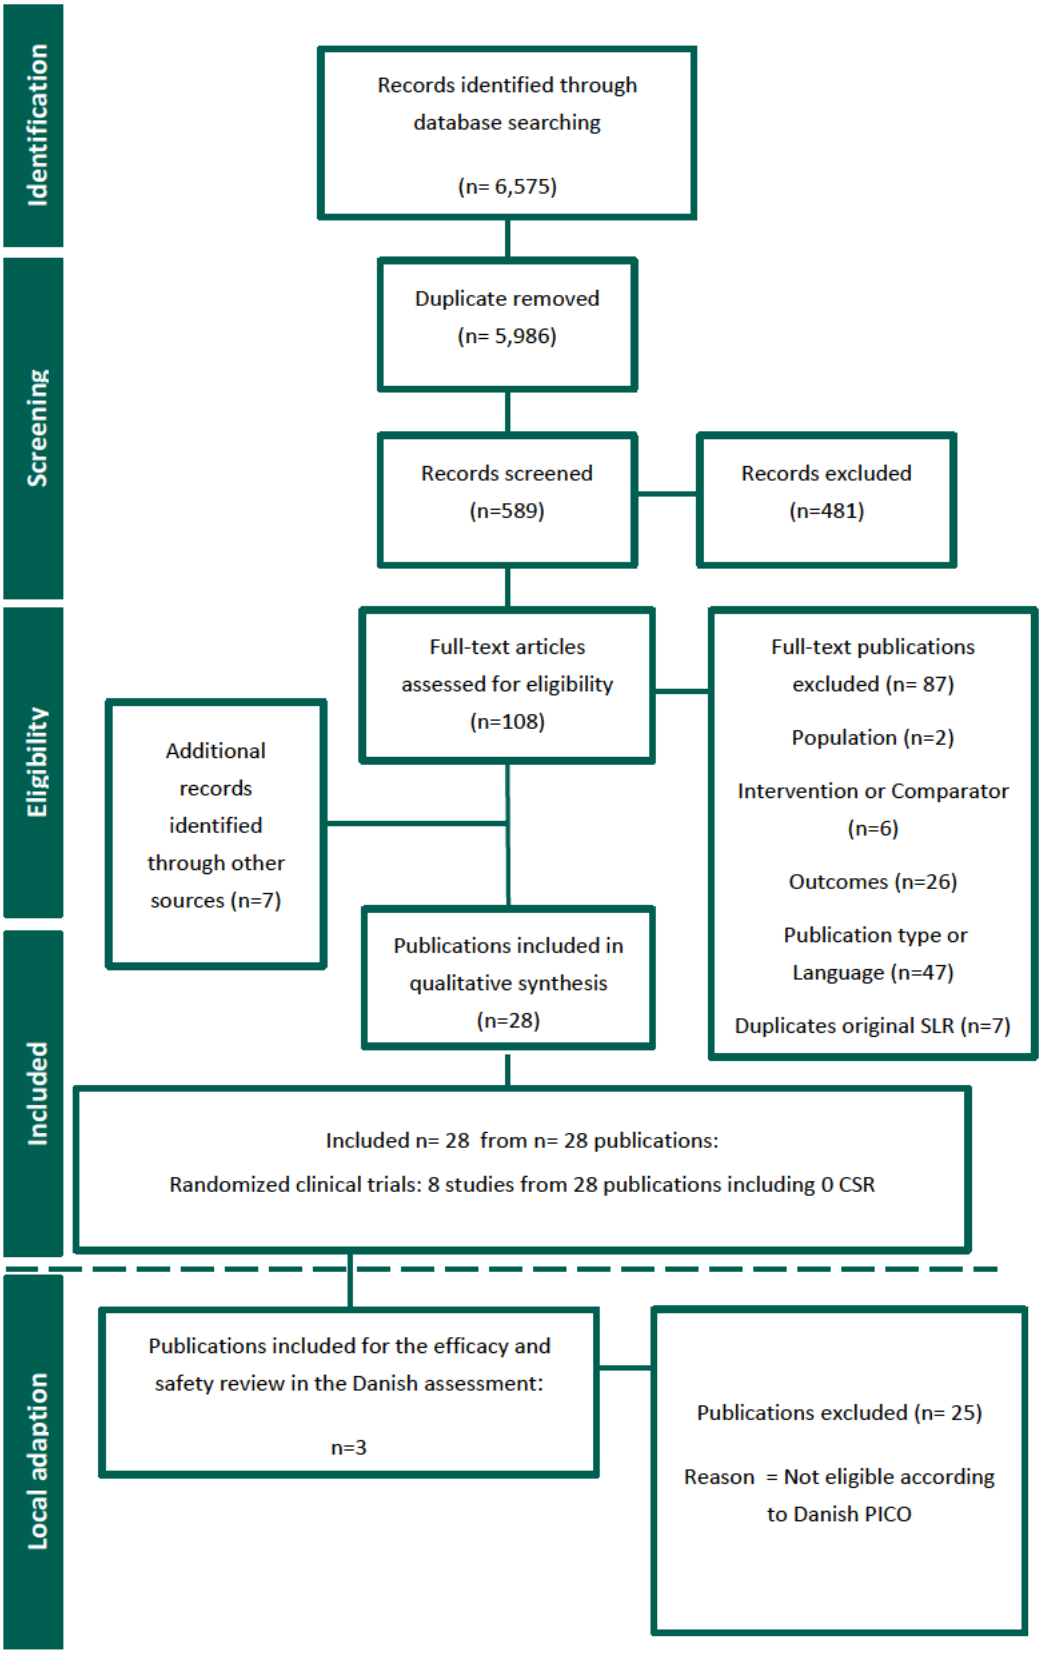

Figure 18 PRISMA flow diagram for studies identified in the updated search, 25 April 2025

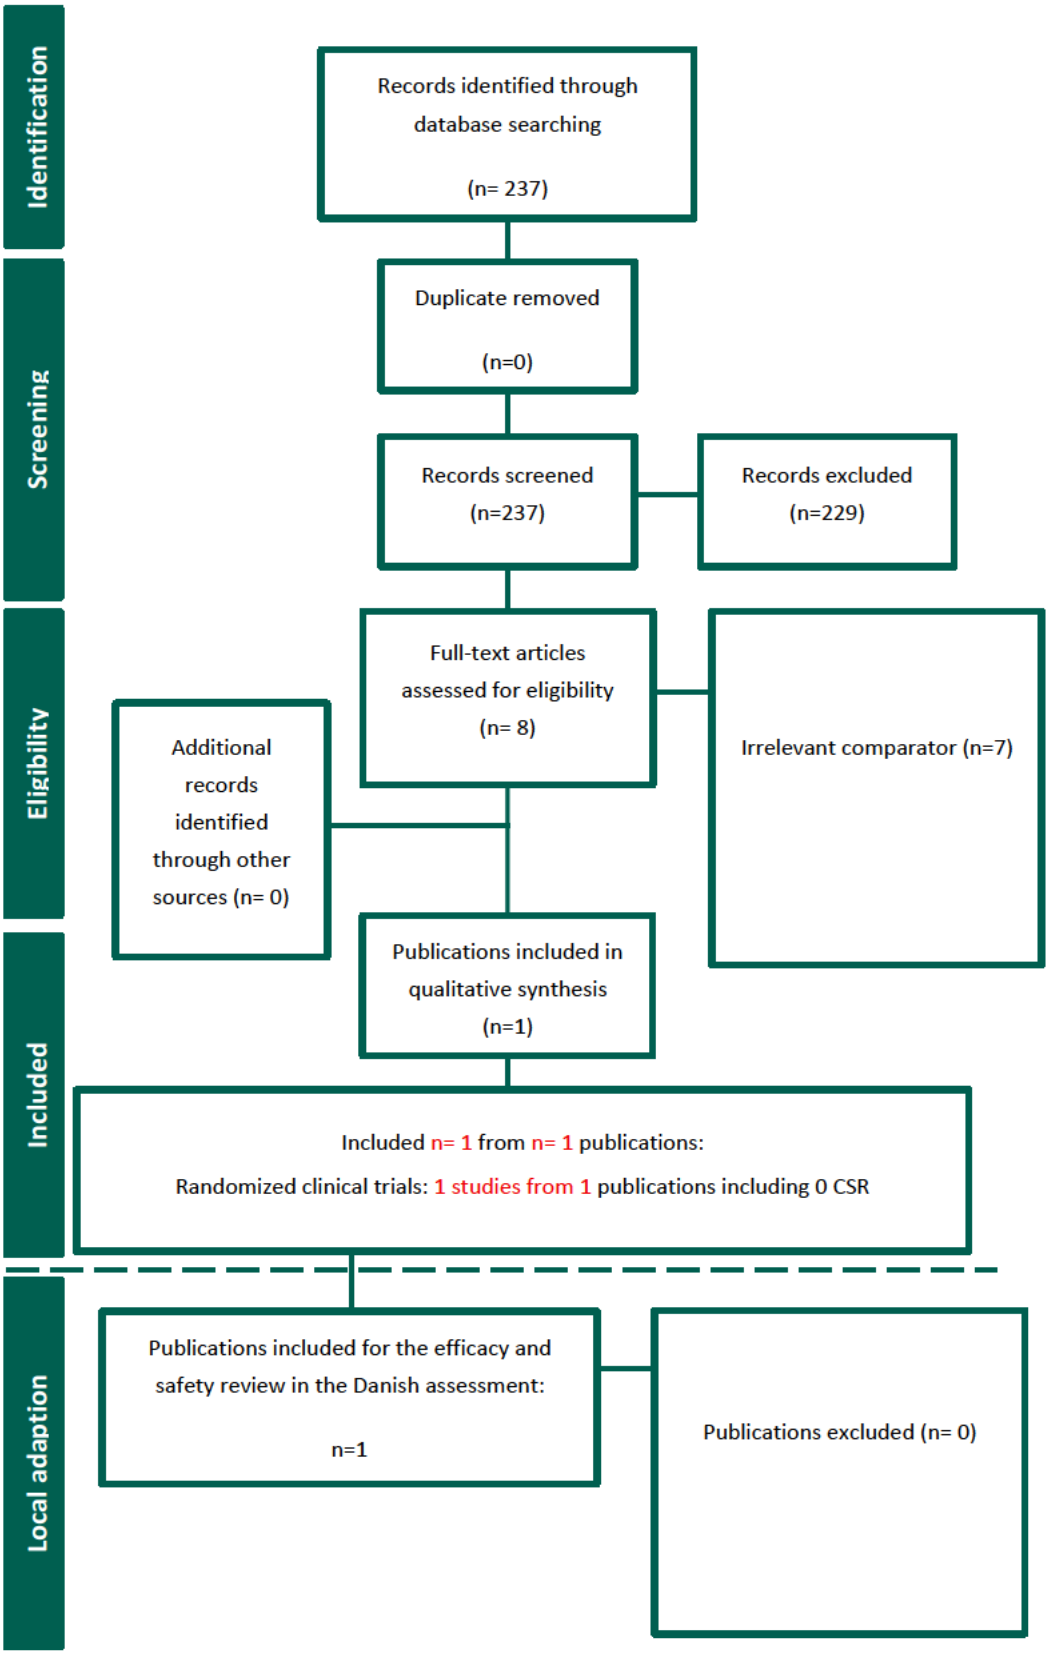

Although the original and updated SLRs identified RCTs across various treatment settings (perioperative, neoadjuvant, adjuvant), only two studies were considered relevant for the ITCs based on the adapted Danish PICO and current SoC:

- AEGEAN as the relevant evidence for a comparison versus neoadjuvant PDC
- CheckMate 816 as the relevant evidence for a comparison versus neoadjuvant nivolumab + PDC
- NATCH as the relevant evidence for the comparison versus adjuvant PDC.

The characteristics of these three studies are presented in Table 86.

Table 86 Overview of study design for studies included in the analyses

Study/ID	Aim	Study design	Patient population	Intervention and comparator (sample size (n))	Primary outcome and follow-up period	Secondary outcome and follow-up period
AEGEAN	Compare neoadjuvant durvalumab+ PDC platinum-prior to surgery, followed by adjuvant durvalumab monotherapy after surgery, versus neoadjuvant placebo + PDC prior to surgery, followed by adjuvant placebo after surgery in rNSCLC	A Phase III, double-blind, placebo-controlled, multi-centre	Patients with resectable NSCLC (stage II to IIIB [N2 node stage] according to the 8th edition of the AJCC Cancer Staging Manual)	Intervention: Durvalamb +PDC followed by PDC Comparator: Placebo + PDC followed by placebo mITT 740 durvalumab + PDC (n=366) or placebo + PDC (n=374)	EFS (up to 5.5 years after first patient randomized) pCR (up to approximately 15 weeks after randomization)	OS and DFS (up to 5.5 years after randomization) mPR (up to approximately 15 weeks) Subgroup analysis of all above outcomes in PD-L1-TC ≥1% HRQoL (from date of screening to 6 months after last dose)
CheckMate 816	Compare nivolumab +PDC to PDC alone in terms of	A Phase III, randomized, Open label	Patients with stage IB–IIIA (7th edition), resectable	Intervention: Neoadjuvant treatment	EFS (up to a median of 30 months) pCR Rate (up to a	OS, mPR TTDM (up to a median of 30 months)

Study/ID	Aim	Study design	Patient population	Interven-tion and compara-tor (sample size (n))	Primary outcome and follow-up period	Secondary outcome and follow-up period
	safety and effectiveness in rNSCLC		NSCLC, no known EGFR mutations or ALK alterations, and an ECOG performance score of 0–1	with nivolumab +PDC Comparator: Neoadjuvant treatment with PDC ITT n= 358 nivolumab + PDC (n=179) PDC (n=179)	median of 30 months)	
NATCH/ NCT00913705	Address whether preoperative PDC + surgery or surgery + adjuvant PDC prolongs DFS compared with surgery alone among patients with rNSCLC	A Phase III, randomized, Open label	Patients with stage IA (tumor size 2 cm), IB, II, or T3N1, NSCLC, considered resectable by the multidisciplinary team	Intervention: PDC followed by surgery (n=199), Intervention: Surgery followed by PDC (n=210). Comparator: Surgery alone (n=210) ITT (n=619)	DFS (51 months)	OS, AE's (51 months)

H.1.4 Quality assessment

The quality of all included RCTs was assessed using the quality assessment tool developed by the University of York's CRD [105]. The quality assessment was completed by one individual and verified by a second independent reviewer.

The quality of non-RCTs and observational studies was to be assessed using the Risk of Bias in Non-randomized Studies of Interventions (ROBINS-I) tool [106]. While non-RCTs were included in the abstract and full-text stage of the review, these were deprioritised moving into the data extraction phase.

As such, quality assessments were not performed for non-RCTs.

H.1.5 Unpublished data

Not applicable.
